Persistence of the bacilli in the throats of infants.—Some observations have been made on this point. The shortest period for the disappearance of the bacilli after the patient's admission to hospital was five days, and the longest forty-two days. A somewhat interesting case was that of patient No. 1820, an adult, in which by the thirteenth day the bacilli had entirely disappeared and recovery was progressing rapidly On the thirteenth day after this, and within one day of the termination of the stipulated period of convalescence, reinfection occurred, as evidenced by the clinical signs of the disease and confirmed by the bacteriological test. By the thirteenth day the bacilli had again disappeared and the discharge of the patient followed shortly afterwards. This was a clear case of reinfection, and, taken in connexion with the ascertained variability in the persistence of the bacilli, shows conclusively that a definite time limit cannot be placed to the period of convalescence, and that though a detention of fourteen days after the disappearance of the exudate is a fairly well chosen term it is sometimes too long for the safety of the patient and often not long enough to prevent infection being carried by those who are discharged. Dr. Park and Dr. Beebe think that the isolation of patients should continue until cultures prove the absence of bacilli, and when such examinations cannot be made at least three weeks should elapse after the disappearance of the membrane. During the past two months, as confidence has been established in bacteriological results, considerable advantage has been taken of such tests in governing the discharge of patients, and in no instance has there been any reason to doubt the correctness of the conclusions.

Diagnosis by examination of the exudate.—The question is often asked whether by a microscopical examination of a smear of the exudate it is possible to make a diagnosis. In many cases a reliable conclusion can thus be formed, but in others it is quite impossible. Failure may arise from the fact that the bacilli are few while other organisms are very numerous, and, as I have before stated, the characters of the Löffler bacillus are in the natural medium often very difficult of recognition. On looking over the records of the last 100 exudates examined I find that the bacillus was noted as being undoubtedly present 36 times, and as being probably present 39 times. In the other cases the organism was either not present or not recognisable. According to this it is possible to make from the exudate a sure diagnosis in at least one-third of the cases, and to form a fairly correct idea as to the nature of about three-quarters. Negative results have not any diagnostic value, as failure to detect the bacilli does not necessarily prove their absence.

Number of species of bacteria found in cultures.—Considering the apparently fertile source it is quite remarkable that so few species are found in serum cultures. Miller isolated more than 100 species from the juices and deposits of the mouth, and it does not seem unlikely that a large proportion of these might reach the tonsils or pharynx. The greater number of such bacteria are derived from food or air, and the mouth organisms proper were found by Miller to be strictly parasitic and not capable of cultivation on artificial media. This may possibly account for the small number of species represented by cultures from the throats of diphtheria patients, and the temperature at which cultures are grown no doubt exercises an inhibitory influence on many species. I have found that the range is confined to about twenty organisms, and the occurrence of some of these is quite rare. The species include Löffler's bacillus and pseudo-form, the pyogenic staphylococci and streptococci, micrococcus tetragonus, white and pink yeasts, the diplococci of Fränkel and Friedlander, Pfeiffer's bacillus, streptococcus articulorum, bacillus mesentericus vulgatus, and other spore-bearing organisms.

Character of pathogenic organisms found.—The following table shows the general character of the organisms present

Digitized by Google

in 188 hospital cases and 60 in private practice. The results are calculated in the nearest whole percentages:—

	Hospital cases.	Private cases.
	Per cent.	Per cent.
Bacillus diphtheriæ	36	21
,, and streptococci ...	11	18
,, and staphylococci	10	6
,, with streptococci and staphylococci...	19	15
Streptococci only	4	16
Staphylococci only (other than micrococcus tetragonus)	6	7
Streptococci and staphylococci ...	12	14
Other organisms	2	2
Löffler's bacillus present	75·5	61·7
,, ,, absent	24·5	38·3

It is commonly supposed that Löffler's bacillus is much more generally associated with cocci than is indicated by this table, but I can only give the facts as observed. It may, however, be explained that there is a bare possibility that the cases of combination are understated on account of the somewhat slower growth of cocci on serum. Observations of the cultures were in all cases made after twenty-four hours' development, except in the case of those set on Saturdays, when twice this time elapsed. Cocci were found to grow in the shorter period, and there is no definite reason to conclude that a longer time in the incubator would have produced a different result. The fact that nearly one-quarter of the cases admitted to the isolation hospital as diphtheria were really not so is a most important one, and points strongly to the necessity for "suspect" wards in institutions of this character. The isolation should be perfect, and all patients should be detained in such quarantine until the results of a bacteriological examination are known. This seldom requires more than twenty-four hours, and by the exudate may sometimes be decided in a few minutes. In the 5611 cultures made in New York from May, 1893, to May, 1894, and representing hospital, dispensary, and private cases, the specific bacillus was found to be absent in 27 per cent of the cases. This agrees fairly well with the results obtained here.

Occurrence of staphylococcus pyogenes aureus.—All cultures were laid aside for fourteen days after microscopical examination so that the golden staphylococcus might reveal itself by its chromogenic character. It was found in 27 out of 188 cases, or about 14 per cent. It is significant that it was present in nearly 19 per cent. of the fatal cases.

Occurrence of micrococcus tetragonus.—The frequency of this organism in diphtheria exudates and cultures calls for special remark. As judged by morphological characters I have found it to be present either in the exudate or cultures in 91 per cent. of the hospital cases examined. This is, I think, a greater proportion than is observed in health; but whether the fact is of any pathological importance I am not in a position to say.

Susceptibility as influenced by age and sex.—The following table affords some data for arriving at conclusions on these points, but it is to be regretted that cases of true and false diphtheria are not separately enumerated. The percentages apply to the ages of hospital patients only.

	Per cent.
7 years and under	50
Between 7 and 14 years	21
,, 14 and 21 years	14
,, 21 and 28 years	10
,, 28 and 51 years	5

The tables of Dr. Park and Dr. Beebe cannot be compared, item by item, with this, but it may, however, be concluded that young children are here much less liable to the disease while adults are more susceptible than in New York. The proportion of females to males was 55 and 44 per cent. respectively, figures which approximate very closely to those applying to New York.

Mortality.—The type of disease prevalent in Toronto appears to be, relatively, of an average character. This is shown by the observed death-rates in various American cities as given in the last report of the Toronto Board of Health. A few of these figures may be reproduced: Cleveland, Ohio, 63·5 per cent.; Des Moines, Iowa, 44·8 per cent.; Brooklyn, N.Y., 36·9 per cent.; Rochester, N.Y., 33·3 per cent.; Boston, Mass., 32·3 per cent.; New York, N.Y., 30·6 per cent.; Philadelphia, Pa., 29·0 per cent.; Detroit, Mich., 28·6 per cent.; Toronto, Ont., 1894, 27·9 per cent.; Toronto, Ont., 1892-94, 22·1 per cent.; Duluth, Minn., 19·0 per cent.; Harrisburg, Pa., 13·0 per cent.; and Toledo, O., 11·7 per cent. General health returns cannot be accepted as being as accurate as those of hospitals, where the facilities for obtaining statistics are complete and under perfect control. It will, therefore, be better to class the death-rate of the isolation hospital with other institutions of the same class, of which a few records are at hand:—

	Per cent.
Sick Children's Hospital, Paris, average of five years	51·70
English hospitals, quoted by Dr. Washbourn, Dr. Goodall, and Mr. Card, average	38·90
Trousseau Hospital, Paris	32·00
Willard Parker Hospital, New York, average of four years	23·77
Willard Parker Hospital, New York, 1894 ...	27·00
Isolation Hospital, Toronto, 1893	19·32
,, ,, ,, 1894	14·05
,, ,, ,, February to June inclusive, 1895	18·08

In the Toronto returns there have not been any deductions for cases which were in a moribund condition when admitted, but every death occurring in the institution has been included. The low rate is highly creditable to Dr. Tweedie, the physician in charge, but, nevertheless, I think the conclusion may be formed that the bacillus is less virulent or the subjects more resistant in Toronto than in many other cities.

Organisms present in fatal cases.—Of the 34 deaths which took place during the last five months there were 33 examinations of exudates, as in one instance the patient died a few minutes after admission and a swab was not taken. In another case, that of an infant twelve months old in a moribund condition from membranous croup, the swab was unsatisfactory. The records of the 32 remaining cases are as follows:—

	Per cent.
Löffler's bacillus only	37·5
,, ,, with streptococci	25·0
,, ,, ,, staphylococci	18·7
,, ,, ,, streptococci and staphylococci	18·7

The staphylococci were in all cases staphylococci pyogenes aurei. No fatal results took place when only cocci were present.

Sex and age in fatal cases.—The proportion of males and females was respectively 44 and 56 per cent., being precisely identical with the ratio of affected cases. Age is represented by the following percentages:—

2nd year	26 per cent.	7th year	15 per cent.
3rd ,, ...	12 ,, ,,	8th ,, ...	3 ,, ,,
4th ,, ...	17 ,, ,,	10th ,, ...	3 ,, ,,
5th ,, ...	15 ,, ,,	13th ,, ...	3 ,, ,,
6th ,, ...	6 ,, ,,		

It will thus be seen that the mortality was 91 per cent. during the first seven years, while the number of patients under that age was 50 per cent. Of the 29 per cent. of patients over fourteen years of age not a single death occurred. Sixty-seven per cent. of the deaths took place within five days after admission to hospital, and 88 per cent. within eight days. The longest period from admission to death was fourteen days.

Relation between organisms present and severity of the disease.—I offer with great hesitancy any remarks on this subject, as some of the results indicated by my investigations are as surprising to me as they doubtless will be to others. I have, however, no reason to question the care with which the bacteriological observations were made, though, in regard to the records of the character of the disease, it may be explained that such were not specially kept for this purpose, but were partly obtained during conversations with the medical superintendent and partly from his notes of cases. Further experience and more perfect records may throw

Digitized by Google

additional light on this subject, but in the meantime I venture to submit what I have up to the present observed. In the following table the cases have been classified as mild, severe, very severe, and fatal, and the proportion with reference to each organism or combination is given in round percentages:—

—	Mild.	Severe.	Very severe.	Fatal.
Bacillus diphtheriæ	46·6	11·2	22·5	19·3
,, and streptococci ...	32·1	17·8	21·4	28·5
,, and staphylococci...	27·2	18·1	22·7	31·8
,, with streptococci and staphylococci	54·3	11·4	20·0	14·2
Staphylococci only	97·3	2·7	0·0	0·0
Streptococci only	100·0	0·0	0·0	0·0
Staphylococci and streptococci ...	100·0	0·0	0·0	0·0

The general belief that the most fatal cases result from the association of Löffler's bacillus with staphylococci or with streptococci is confirmed by the above figures, and the former combination is the most serious. It is, however, extraordinary that when both cocci are present with the Löffler bacillus the death-rate is apparently reduced by one-half. This would indicate an antagonism between the combined cocci and the bacilli—a supposition which I do not care to urge until further evidence is obtained, and this I shall take particular pains to procure. There are other interesting deductions which might be drawn from the above statistics, but I shall not further trespass on patience which must be already overtaxed.

Toronto.

A CLINICAL STUDY OF THE ANTI-SUDORIFIC PROPERTIES OF PICROTOXINE.[1]

BY DR. M. SEMMOLA,

PROFESSOR OF CLINICAL THERAPEUTICS OF THE ROYAL UNIVERSITY OF NAPLES AND SENATOR OF THE KINGDOM OF ITALY.

THAT most important function of the skin, perspiration, is, like all other vital functions, regulated by various factors. Many different causes may provoke its augmentation or diminution, such as the surrounding temperature, excess of water in the blood, extreme activity of the heart, dilatation of the peripheral vascular system, some medicinal substances, several pathological states, and, finally, the influence of special secreting nerves. Eliminating accidental causes, those which remain to preside over the sudoriparous secretions are the bloodvessels and the system of secreting nerves, which are almost always closely dependent on each other; in fact, a vaso-dilatation often succeeds an excitation of the secreting nerves. However, perspiration, which often takes place when the skin is pale, like that due to strong moral excitement and the cold sweat of the death agony, proves that the secreting fibres can act even when the constricting fibres of the vascular system are excited. That there are special sudoriparous nerves independent of the vaso-motor system has been demonstrated by the famous experiments of Goltz, Kendall, Luchsinger, and Ostruomon; indeed, the secretion of perspiration has even been verified in the secreting nerves of a limb just amputated. Nor are secreting nerves the only known cause, for the presence of sudorific centres has been discovered. Thus in the cat a lumbar centre has been shown to influence the posterior limbs; a cerebral centre the anterior ones (Vulpian, Luchsinger, Nawrocki, and Ostruomon); and a bulbar one, which influences all four limbs (Marmé and Adamkewiez) and may in a cat cause perspiration of these limbs to continue up to three-quarters of an hour after its death. At other times perspiration is in direct proportion to the quantity of blood distributed on the surface of the skin, as has been shown by the celebrated experiment of Dupuy, who, after cutting the sympathetic nerve of a horse, saw the correspondin the neck break out into a profuse sweat; and als of Nitzelnadel, who galvanised the cervical sy nerve of a man and observed the consequent perspiration.

The cause of the increase or diminution of secretions being so various, it is clear that there m differences in the methods by which several s influence this function. Whether they act direct bloodvessels or the excitability of the nervou system, or simultaneously on both these factors always obtain by their means an increase or dim perspiration. We have substances in our Pha which act on the cutaneous functions in utterly manners and by various processes. Thus there a agents more or less efficacious in producing diapho vary in their mode of action because their i variously developed; they may act by increasing of blood, as in the case of copious draughts of ho by exciting the action of the heart, as in abundan warm spirituous liquors; they may, again, act b ing the sudorific centre, as in muscarine, phy nicctine, or acetate of ammonia, or the wh secreting nervous apparatus, both central and may be stimulated as by pilocarpine; and, vaso-motor organs may be paralysed, as by antin ipecacuanha, &c., and a hyper-functionabil apparatus produced. On the other hand, we therapeutics many substances that by means different actions have antisudorific properties. and cold water, *douches écossaises*, &c., by the vascular system, tend to re-establish the peripheral vessels and so diminish the secretio Tannic and gallic acids would produce an irr on the vaso-motor centre (Fikentscher) and action on the vessels and sudoriparous g diminishing transpiration and evaporation. lead has a styptic action; white agaricus and agaric acid (Haen, Barbut, Piermy, To Lauchmann, Hoffmeister, and others) possess effect on the peripheral apparatus of secretion. Camphor and camphoric acid (Leu, Combenale) act as general stimulants to system; atropine paralyses the secreting nerves picrotoxine acts by first exciting the vaso-m centre and then consecutively constricting (Planat, Bokai, and others); all these dr or more rarely arrest the secretions. T therefore, possesses several antisudorific reme they differ in their actions so should they l therapeutic indications, for increase of pers arise from various causes which may ha different actions. Before, therefore, we antisudorific treatment it is necessary to form ception of the pathogeny of the disturbance tions; and, according to whether the nervous s the vaso-motor system, or the smooth fibres vessels, &c., enter into play, we must choose ceutical substance which, when absorbed, can t counteract the disturbances which in that e have caused the diaphoresis. In other terms, an ephidrosis due to excitement of the sudori system we must have recourse to the r agaricine, atropine, &c., which have an inhibit compensating the increase of function; or when we believe the ephidrosis is caused by p vaso-motor centre we should administer ex such as picrotoxine; and, lastly, if there is vascular tone from peripheral disturbance hydropathy, which has such a marked action of the bloodvessels. Guided by these ideas truly splendid results in cases where many been uselessly experimented with without peutic indication, which should especiall scientific practice. I will briefly report a cl the greatest importance in the nature of f tion, and the rational treatment followed, complete recovery.

The patient was a woman aged forty-th at home. She had no morbid history of n ditary or acquired. In December, 1893, sh with high and persistent fever, headache, s still slighter expectoration. These morbid c

[1] A paper read at the Institution of Clinical Therapeutics of the Royal University of Naples, and edited by Dr. Carlo Gioffredi, assistant at that Institution.

Digitized by Google

ceased, she continued to remain in bed on account of great general prostration. Her appetite and digestion were, however, well preserved. During convalescence, which is always long after influenza, she gradually began to show a great tendency to perspire, doing so profusely without the smallest muscular effort, even though it was in the middle of winter. This tendency constantly increased, until streams of perspiration poured off the patient, when she was only dressed and covered as lightly as if it were summer time. Together with this there were frequent peripheral vaso-motor disturbances, chiefly shown by livid red patches more or less extended and persistent. The skin was cool on account of the constant cutaneous evaporation. On examination of the nervous system no alteration worthy of note presented itself either functionally or subjectively. On careful examination of the heart an increase of the transverse diameter was noted, and a systolic murmur at the apex, with accentuation of the second sound over the pulmonary area. The other organs were normal. There was anæmia caused by the great drain on the system, and the general state of the patient was very low. Several antisudorific remedies had been tried to counteract this morbid process — atropine, agaricine, camphor, camphoric acid, &c.—but all had proved inefficacious. If we except the insufficiency of the mitral valves, the most important clinical points in the history were the preceding influenza, ephidrosis, cutaneous patches, and the prostration. The onset of perspiration had occurred immediately after a serious attack of influenza with great weakness, and had progressively developed, notwithstanding that the other phenomena of the disease had entirely disappeared. I considered that we were treating a perspiration due to paresis, more especially caused by some of the many toxines which are often superadded to influenza, and which in this case exerted their action on the sudoriparous centre and the vaso-motor centre of the bulb—a frequent seat of action of these toxines, as has already been demonstrated by the examination of the urine of patients suffering from it.[2] The livid red marks on the skin were certainly due to vaso-motor paresis, and so confirmed the diagnosis. And this was why atropine had proved useless; it had no marked action on the peripheral bloodvessels, which were the actual cause of the perspiration. Agaricine had been equally inefficacious, as it acts in much the same way as atropine; indeed, we may add that this drug, having, according to Hoffmeister, a peripheral action on the vaso-motor centre, would certainly have aggravated in this case the pathogenic cause of the ephidrosis. Starting, then, from this conclusion—i.e., deeming that the perspiration in this patient must be referred to exhaustion of the vascular tone from paresis of the bulbar vaso-motor centre — I prescribed picrotoxine as a remedy potent to stimulate that centre, which was weakened by a special toxine—in fact, a treatment founded on elective antagonism. The results obtained were in complete accordance with my predictions and fully confirmed the theory I had formed of the pathogeny of this singular functional disturbance. Scarcely three days after the picrotoxine had been given (in doses of half a milligramme twice a day) the sweats gradually diminished and entirely disappeared on the eighth day of treatment, while hitherto they had been obstinate against all other remedies. The effects of paralysis of the vaso motor centre also entirely ceased with the perspiration, and by degrees the patient lost all sense of general weakness, which was the effect of the drain made on the system by profuse sweats, and returned to complete health.

The rational therapeutic indications which ought to form the basis of modern clinical study have in this case a marked confirmation. Antisudorific therapeutics, like all other therapeutics, should no longer be empirical. To varying pathogeny, to the different processes of production *en rapport* with the etiology, different indications should correspond. Now that physiology and pathology have shown us the various causes which may originate disturbance in the secretions of the sudoriparous glands, and pharmacology has enlightened us on the ways in which different substances act on the functions of the skin, every form of ephidrosis should no longer be treated indifferently with any chance antisudorific remedy, or by passing all such drugs in systematic review, as is frequently done in practice. It is needful to study the pathogenesis of the special morbid form under treatment, and thus choose that remedy which most reasonably suits the case.

ON CURETTING THE UTERUS IN CASES OF PUERPERAL SEPTICÆMIA.

BY ALEXANDER DUKE, F.R.C.P., L.R.C.S. IREL.,
FORMERLY OBSTETRIC PHYSICIAN TO STEVENS' HOSPITAL, DUBLIN; EX-ASSISTANT MASTER, ROTUNDA HOSPITAL, DUBLIN.

HAVING been present during the interesting discussion on the preventive treatment of puerperal fever (improperly so-called) at the last meeting of the British Medical Association (Obstetric Section), I was surprised that no allusion whatever was made to the treatment in such cases by curetting with blunt wire the cavity of the uterus. I am under the impression that I was the first to suggest this proceeding in the *British Medical Journal* in 1889 and in THE LANCET in 1890, and my name appears in this connexion in Neale's valuable "Digest" (Section 1595), third edition. This suggestion (which I have on several occasions acted on with satisfactory results, and which I still recommend in suitable cases) was commented on in a pamphlet published by Mr. E. Tenneson Collins (Cardiff) in 1894, entitled, "Pathological Objections to Curetting the Uterus in Puerperal Fever," in which he condemns this proceeding. On the title-page he states: "This paper was the outcome of a suggestion by Dr. Alexander Duke to curette the uterus in puerperal fever, followed by frequent irrigation, and he argues on a supposed analogy between the puerperal uterus and one affected by chronic endometritis." Mr. Collins's arguments, however, are not convincing to me, as he evidently supposes I use an instrument sharp enough to produce a breach of the surface, which I am most particular to avoid, by using only a blunt wire loop which I can attach to an irrigation tube if required. A French gynæcologist, M. Rapin (Lausanne), who has adopted this treatment, says:[1] "Everyone admits the utility in cases of retention of practising curettage as soon as symptoms of endometritis set in (fever, fetid lochia), in order to relieve the womb of the tissues which would form a favourable field for the development of microbes. This curettage is superior to cauterization or intra-uterine injections." I certainly consider that curetting with blunt wire (followed by drainage if necessary) is much less dangerous than intra-uterine injections alone, and for the reason that the micro-organisms which exist in these cases are found in far greater numbers near the vaginal outlet, and consequently would be much more likely to be carried upwards into the uterus by syringing than by the curette. I cannot, therefore, agree with the last sentence in Mr. Collins's pamphet: "It is unjustifiable to curette the uterus in puerperal fever." For my own part I much prefer to have recourse to curetting than to rely on the old treatment by drugs alone. I cannot help thinking that the antiseptic treatment in midwifery would be seldom required if more attention was paid to the aseptic, one of the most important plans being thorough flushing of the entire genital tract directly after labour. M. Rapin states that "After each delivery there remains a more or less large quantity of tissue in the uterus destined to undergo fatty degeneration and mortification. This is the decidua vera, and furnishes the greater part of the materials constituting the lochia." Is it not common sense, I ask, to remove this *débris* by flushing and so entirely take away this primary source of mischief, which later, if left (more especially by contact with a broken surface, such as a lacerated cervix or perineum), might perhaps inoculate the patients and set up puerperal septicæmia? Those who have never taken the trouble to thoroughly wash out the uterine cavity directly after labour (the time it can be best and most easily accomplished) can have little idea of the amount of *débris* which, if left behind, must take a considerable time to be expelled, and is certainly likely, to say the least, to prove a source of danger to the lying-in patient. In washing out the uterus I place the patient on the back and use either a syringe or douche. I employ plain water at a temperature of 110° F. which has been previously boiled; a little tincture of iodine may be added if preferred. I keep the left hand over the uterus while the fluid enters the cavity; the cervical canal is patulous, and therefore offers no resistance to the the introduction of the tube, there being sufficient room for the return current. This treatment is stimulating, cleansing,

Digitized by Google

and hæmostatic. In fact, there is everything to recommend the proceeding, and nothing (that I know of) to forbid its general adoption in all cases of labour and miscarriage.

Cheltenham.

ON GRANULAR KIDNEY FOLLOWING SCARLATINAL NEPHRITIS.

BY J. DIXON MANN, M.D. ST. AND., F.R.C.P. LOND.,
PHYSICIAN TO THE SALFORD ROYAL HOSPITAL.

THE absence of any essential distinction between the pathological processes concerned in the production of the different forms of Bright's disease is once more forcibly demonstrated by the following case. The patient was under my observation from the time she was attacked with nephritis until her death—a period of twenty-eight years.

In 1866 a girl aged fourteen years, previously healthy, had an attack of scarlet fever followed by nephritis and dropsy. There was nothing unusual in the course of the acute stage of the kidney disease; it subsided in a few weeks, and the patient regained her former state of health except that albumin continued to be present in the urine. From this time until her death, which took place in October, 1894, the urine was examined six or eight times every year, and albumin was found to be present on every occasion. For seven or eight years after the original attack the patient had occasional subacute attacks of nephritis, during which the urine became scanty, cloudy, and smoky, or red; at such times it contained numerous hyaline and fatty casts. In the intervals the urine was clear, of medium colour, and was free from excessive deposit, only an occasional cast being present. In some of these attacks there was considerable œdema of the hands and feet as well as of the face; at all other times no trace of œdema was present. These attacks usually followed exposure to cold; sometimes they occurred without any ascertainable cause. Each attack lasted about two or three weeks; they were entirely absent during the later period of the patient's illness. With the exception of occasional slight attacks of bronchial catarrh and of subacute rheumatism the general health was good. As a girl the patient was of a rosy complexion, and she retained the greater part of her facial colour throughout life; she never became anæmic. She was moderately stout and did not lose flesh until the last year of her life. At the age of twenty-eight she married, but had no children. From 1866 to 1880 the urine invariably contained a considerable amount of albumin, varying from 0·2 to 1 per cent. Somewhere about the year 1880 a change was noticed in the character and the quantity of the urine; in place of being of medium, or rather higher than medium, colour, and of moderate amount—thirty-four to forty-five ounces daily—it became of lower specific gravity, 1005 to 1010, paler in colour and more abundant, eventually reaching sixty to eighty ounces daily. The percentage of albumin also diminished, never exceeding 0·3 per cent. Casts were now very rarely, and blood-corpuscles never, found, the urine being almost free from deposit. From time to time observations were made as to the relative amounts of serum albumin and serum globulin in the urine. The proteid quotient was found to range within wide limits, being sometimes as high as 35, and at others as low as 0·8. The only striking feature observed was that the mean of the quotient tended to fall as the case advanced. The diminution was by no means regularly progressive, but, taking the whole series of observations, there was a decided drop during the last year; this was probably due to the altered constitution of the blood plasma induced by the disease. The daily excretion of urea did not materially deviate from the normal, although during the latter part of the patient's life the percentage of urea in a given volume of urine was diminished. A few weeks before death a considerable reduction in the amount daily excreted took place. The arterial tension gradually rose as time went on and the left ventricle became hypertrophied. In 1888 a mitral systolic murmur was observed. In September, 1894, the patient was troubled with persistent headache and sleeplessness, having previously been a heavy sleeper. Retinal hæmorrhages had been observed a short time before. She then became worse, and, after having been unconscious for several days, died from uræmia in October, 1894.

Post-mortem examination showed that the heart was considerably hypertrophied, especially the left ventricle. The liver was rather large and hyperæmic; it showed no cystic changes. The kidneys were very small; the left weighed two ounces, and the right a few grains under two ounces. They were dark-red in colour, without any white or yellow spots or patches. I am indebted to the kindness of my colleague, Professor Sheridan Delépine, for the following minute description of the kidneys: "Both the kidneys were small, measuring three inches and a half in length and one inch and three-quarters in width. Generally speaking they were normal in shape. The ureter and pelvis were of normal size. The capsule could not be stripped off without the substance of the cortex being torn and a number of cysts opened. The denuded surface of the cortex was very granular, cystic, and congested; some of the cysts projected much beyond the surface of the organ, the largest measuring about half an inch in diameter. This cyst contained a thickish, colloid-looking material. Microscopically examined, the organ presented all the appearances generally associated with the term "granular kidney." The capsule was thickened and rough on its external surface, indicating fibrous induration of the perinephral tissues. The interstitial tissue of the cortex was much increased, especially in the region of the pyramids of Ferrein, where the tissue was very transparent, finely fibrillated, and œdematous or myxœdematous looking; here and there it was moderately cellular, but there was no evidence of any recent small-celled infiltration. In the labyrinth the fibrous tissue was more scanty, denser-looking, and more coarsely fibrillated. In the medulla the increase of connective tissue was also very well marked and the œdematous look more striking; in many places the bloodvessels (capillaries) were separated from the collecting tubes by a layer of connective tissue thicker than the diameter of the tubules or of the blood vessels themselves. The large arterial arches and many interlobular arteries were little altered, but were surrounded by a large amount of adventitious connective tissue. The smaller arteries, especially the terminal branches of the interlobular arteries immediately under the capsule, showed great thickening of their walls, most marked in the tunica intima, which in some exceptional cases was so thick as nearly to obliterate the lumen. The veins were generally dilated and also the capillaries. The Malpighian glomeruli and the capsule of Bowman were almost without exception scarcely distinguishable owing to fibrous transformation; those which remained distinct were in a state of fibro-hyaline degeneration; only a few Malpighian bodies appeared to be capable of performing any function. The convoluted tubules were mostly dilated, giving to the labyrinth an appearance resembling that of lung parenchyma. In many of the dilated tubules the atrophied epithelium could be recognised; in some the epithelium was lying loose in the lumen, in others the atrophied cells were pressed against the basement membrane by a mass of colloid matter in which cells more or less degenerated or vacuolated could be recognised. Some of the most dilated tubules formed cysts quite distinct to the naked eye, reaching in one instance a diameter of half an inch. In a small proportion of convoluted tubules showed considerable atrophy. The straight tubules in the medullary rays were much atrophied, and here and there large cysts could be found in the labyrinth. In the papillary region of the pyramids of Malpighi some of the large collecting tubules were also much dilated."

Professor Delépine's report places this case among those in which, as a sequence of acute parenchymatous nephritis, a pathological condition is met with indistinguishable from that associated with the common type of granular kidney. The resemblance is complete; the tissues attacked, the character of the changes produced are identical. It is necessary to emphasise this lest the case should be regarded as one of arterio-sclerotic atrophy. In this form of contracted kidney the changes are almost entirely limited to the renal arteries and their branches. The arteries become gradually obliterated by thickening of the intima, the glomeruli supplied by them are rendered functionless, and in consequence, atrophy along with the tubules connected with them; localised patches of cicatricial contraction of the cortex ensue, and these may be so numerous as to involve the entire cortex, producing naked-eye appearances which resemble those of the ordinary cirrhotic kidney. The difference consists in the limitation of the morbid process to the renal arteries; there is practically no increase of the connective tissue, nor are Bowman's capsules thickened.

Digitized by Google

case the connective tissue throughout the cortex was greatly increased, Bowman's capsules were almost obliterated by fibrous invasion, and the larger and many of the interlobular arteries were but little altered, only the intima of their terminal branches being thickened. That the original disease which attacked the kidneys in the case under notice was of the acute parenchymatous type the clinical history clearly shows. That after a time it merged into chronic parenchymatous nephritis is equally obvious, and that the ultimate result was a condition absolutely indistinguishable from the ordinary granular kidney is demonstrated by Professor Delépine's report. The continuity of the morbid processes is established by the fact that albumin was always found to be present in the urine during the whole of the post-scarlatinal period of the patient's life, and also that the urine gradually approached in character the urine from an ordinary case of contracted kidney. During these twenty-eight years the kidneys were undergoing a series of changes, the character of which altered as time went on. The primary disease being scarlatinal nephritis would chiefly attack the glomeruli, but accompanying this there would also be more or less diffuse interstitial inflammation. The usual course is towards recovery or to comparatively early death. In the latter case the effect of the inflammatory processes on the vascular parenchyma is to produce more or less rapid and permanent loss of function, which ends matters forthwith; or, when the inflammation is less destructive, it leads to chronic changes which are also to a preponderating degree parenchymatous. Any changes that occur in the interstitial tissue are of negligible quantity, simply because, being of much slower type, they have not time to assert themselves before the more vital structures succumb. In my case, however, neither the original attack nor the subacute attacks which followed were of such virulence as to permanently damage the glomeruli beyond a point which was consistent with considerable duration of life. The necessary factor—time—consequently came into play; interstitial hyperplasia took place, with subsequent contraction of the overgrowth, together with the other indurative changes met with. It would thus appear that the condition found after death was simply the ultimate expression of one not unfrequently seen, in a modified form, in cases of chronic parenchymatous nephritis (large white kidney), which have survived rather longer than usual. In such cases some amount of fibrous hyperplasia of Bowman's capsules, along with cicatricial contraction of the cortex, which may reduce the kidney to less than the normal size, are by no means uncommon. The essential feature of the case was its singularly protracted course, which allowed the cirrhotic changes to reach a most advanced stage.

Manchester.

ON THE VALUE OF BICHROMATE OF POTASH IN CERTAIN AFFECTIONS OF THE STOMACH.

BY J. B. BRADBURY, M.D. CANTAB., F.R.C.P. LOND.,
DOWNING PROFESSOR OF MEDICINE IN THE UNIVERSITY OF CAMBRIDGE; PHYSICIAN TO ADDENBROOKE'S HOSPITAL.

I BROUGHT back with me from the meeting of the British Medical Association at Clifton in August, 1894, a small box of soft gelatine capsules—prepared by Messrs. Duncan, Flockhart, and Co. of Edinburgh—each containing one-tenth of a grain of bichromate of potash. With the box were no directions, and for some months I could not make out in what diseases they were intended to be used. At the beginning of this year Professor Fraser of Edinburgh kindly sent me a paper which he read before the International Medical Congress at Rome [1] on the use of this drug in certain affections of the stomach, and I soon had the opportunity of testing its value in the case of my parlour-maid.

CASE 1.—In February she had an acute attack of gastralgia, which neither bismuth, morphia, nor iron, with the most careful dieting, would alleviate. She had had many similar attacks before and had always been relieved by a powder containing bismuth, opium, magnesia, and soda, or by iron. The pain was so severe that she was compelled to give up her work; it came on usually *directly* after eating, occasionally before, and was relieved by vomiting. She was slightly anæmic, but the bowels and catamenia were fairly regular. I determined to try the capsules, and after taking one three times a day for two or three days on an empty stomach she became much better and continued to improve. She has kept quite well ever since. Altogether she took two boxes of the capsules, each box containing about twelve.

CASE 2.—A man aged thirty, married, was admitted into Addenbrooke's Hospital, Cambridge, on April 3rd of this year suffering from attacks of vomiting after food. Generally the attacks came on many hours (from ten to twelve) after a meal, and most often occurred in the early morning. No pain was felt after food had been taken, but occasionally bright blood was found in the vomited matters. The Sunday before admission he brought up two tablespoonfuls of blood in the vomit. He had been troubled with these attacks of sickness for three years, and in consequence had been almost constantly an in- or out-patient at the hospital. Relief was obtained for a time, but the attacks quickly recurred. The patient was somewhat wasted, but there was no evidence of any other disease. He was of temperate habits. He was dieted on beef-tea and milk, and the day after admission was given one capsule of potassium bichromate (one-tenth of a grain) three times a day. He vomited on each occasion an hour after taking the first three capsules and once four days afterwards. On April 10th, one week after admission, he was allowed bread, on the 13th fish, and on the 17th pudding. On April 28th he left the hospital greatly improved in every respect, having gained weight and the power to take solid food.

CASE 3.—A woman aged forty-six was admitted to Addenbrooke's Hospital on April 17th last suffering from pain in the stomach and vomiting. These symptoms commenced seven years ago and had been more or less present ever since. She had lost flesh and occasionally had brought up dark blood in the vomit. She was the mother of eighteen children, of whom ten were living, and there was a pronounced family history of phthisis on the father's side. When admitted the patient presented a somewhat wasted appearance; the gastric pain was constant, being worse after food, and vomiting occurred after every meal. There was tenderness in the epigastrium and right hypochondrium, but no tumour was felt. The tongue was slightly coated and the appetite poor; the bowels were regular. She was put on a milk and beef-tea diet, but no improvement occurred, and three days afterwards was ordered one potassium bichromate capsule (containing one-tenth of a grain) three times a day, with an occasional dose of an elixir of cascara sagrada. During the night she vomited once, but the next day she was free from pain. The improvement continued. On April 28th, eight days after commencing to take the capsules, fish was added to her diet, and on May 5th full diet was allowed. This, however, produced retching and abdominal discomfort, and it was therefore found necessary to replace the meat by fish. Subsequently the patient gradually improved and was finally discharged on May 11th. Reporting herself at the hospital two weeks later, she stated that the improvement had continued and that she was practically well.

CASE 4.—A man aged fifty-nine was admitted into Addenbrooke's Hospital on April 6th last complaining of a constant gnawing pain in the epigastrium and occasionally shooting into the loins. This first commenced about a month before Christmas and had continued ever since. It was sometimes worse about an hour after food, but there was no definite relation to meals. The patient stated that he had lost two stone since Christmas; he had never vomited, and no family history of cancer was obtained. The bowels were constipated. On examination of the abdomen the superficial veins were found distended; an ill-defined roundish mass, slightly tender, was felt in the region of the umbilicus, but no enlargement of the liver or spleen could be detected. A trace of albumin was found in the urine. On admission he was put on a milk and beef-tea diet, a purgative and a simple enema being also given. No improvement occurred. On April 10th potassium bichromate capsules, one three times a day, were given. Improvement almost immediately followed; the pain abated, the patient gained weight and was soon discharged, being able to take solid food with impunity.

CASE 5.—A young woman aged eighteen first consulted me on May 14th, 1892. Her symptoms were pain after eating and extending between the shoulders, occasional vomiting, but no hæmatemesis. She was afraid to eat on account of the pain. The bowels were very costive. The catamenia were regular. She had not been well for two

[1] Vide THE LANCET, April 16th, 1894.

Digitized by Google

years. There was slight tenderness in the epigastric region. These symptoms were relieved by a mixture containing bismuth, morphia, and magnesia, and by careful dieting. Later in the year she became anæmic and the catamenia irregular, and she was successfully treated with iron pills. In August, 1894, she had a recurrence of the pain, vomiting, constipation, and tenderness in the epigastrium, and the symptoms were again relieved by a bismuth and morphia mixture. The catamenia were, however, irregular, often not reappearing for seven or eight weeks. On March 23rd, 1895, she came to me again with the same symptoms, and I gave her the bichromate capsules. I did not see her again till May 18th, when she informed me that the capsules had stopped the vomiting and that she had had neither sickness nor pain for about seven weeks. Her appetite was better, the bowels more regular, and she felt stronger. She is still continuing to take the capsules.

The next two cases were not successful.

CASE 6.—A man aged about fifty consulted me in December, 1889, for pain in the stomach, or rather a feeling of rawness and soreness. The bowels were regular and the tongue a little coated. He was benefited by a mixture containing bismuth and belladonna. In May and June of the following year the pain, rawness, and soreness returned, and sometimes the pain was very acute. Morphia and bismuth gave him some relief, but a good holiday did him more good than anything. He did not consult me again till April, 1895, when he had the same symptoms as before. His appetite was fair, but he was afraid to eat on account of the pain. I prescribed the bichromate of potash capsules for him, and although he tried them for a fortnight he received no relief. I then placed him upon a mixture containing bismuth, sulpho-carbolate of soda, and Fowler's solution; but I have not seen him since and do not, therefore, know the result.

CASE 7.—The patient was a woman past the menopause who had had at times for years severe attacks of gastralgia, which a powder containing bismuth, magnesia, soda, and compound powder of opium usually relieved. I gave her the capsules, and I thought at first they were benefiting her; but she had a most excruciating attack of pain, and I was obliged to place her upon a strict diet and a bismuth, morphia, and magnesia mixture.

The cases are few in number, but they show the extent of the action of potassium bichromate in the treatment of gastric conditions. That this salt is beneficial in many cases of dyspepsia can no longer be doubted. Both Vulpian and Fraser have described successful cases, and Hare of Philadelphia also mentions its value. Vulpian's cases[2] exhibited a variety of symptoms, but were all of a more or less chronic character. In some patients pain was a prominent symptom, in others there was none; in some no tenderness existed, others on the contrary presented tenderness more or less severe and localised; anorexia was not infrequently absent, and in some blood was found in the vomit. Other cases of his had decided dilatation, and a few were probably cases of malignant disease. In some of the last-named cases the relief was so marked that he thought it was probably due to a specific effect, and consequently he gave the drug in cases of uterine cancer, but without benefit. He thinks, however, that the drug is most useful in those cases of dyspepsia which simulate cancer. Like myself, he does not appear to have been always successful, for in speaking of one case he says, in parenthesis, "I speak only of those cases where I obtained great amelioration." Fraser's cases are very similar to those of Vulpian and my own. They presented very dissimilar symptoms, or perhaps I ought to say combinations of symptoms, but nearly all of them might be classed under what is termed "chronic dyspepsia." Ten of his cases were diagnosed as gastric ulcer, but in all the cases more or less relief immediately followed the potassium bichromate treatment. In cases of anæmia the gastric disturbance was relieved or cured, but the drug had no effect upon the condition of the blood. When iron was administered, however, the amount of hæmoglobin and number of corpuscles very quickly increased, and the patient soon became well. The salt does not appear to possess any great hæmostatic power, and it is practically useless in the treatment of ordinary hæmatemesis. Although the therapeutic value of potassium bichromate is thus evidenced, a rational explanation of its action—that is, its pharmacology—is by no means easy. At the present time numerous cases of poisoning by this salt, of a more or less acute character, are on record, and many experiments (by Orfila, Vulpian, and others) have been made to determine its pharmacological action, but it is peculiarly difficult to draw conclusions from the administration of toxic doses as to the action of minute doses administered therapeutically. Shortly, potassium bichromate in large doses acts upon the nervous system and secreting structures. Administered by the mouth, subcutaneously, or intravenously, it almost invariably produces vomiting and often diarrhœa. After death congestion and ecchymosis of the alimentary tract are usually found. It is, in fact, an irritant poison. As it produces such profound changes when given in toxic doses it is not improbable that in smaller doses it may act as a stimulant to the secretary cells. In all cases of chronic dyspepsia the activity of the gastric cells is modified; indeed, it is usually this modified condition which keeps up the dyspepsia. The stomach is not doing its work, the blood-supply is less active, the structure of the mucosa is changed, and the active cells are perhaps degenerated and are further degenerating. What we wish to do, after removing the cause if this still exists, is to bring back the cells to a normal condition. Sometimes this can be done, but often the pathological changes are such as to make it impossible. In such cases, however, we may alleviate the condition and by careful dieting the patient may continue in apparent health. It is very probable that potassium bichromate acts by modifying this nutritive activity of the various gastric cells, at the same time increasing the blood-supply and producing a more normal digestion. Vulpian thinks it acts on the terminations of the nerves in the mucous membrane, and Fraser also thinks that this may be a factor in its therapeutic action. It has been shown to possess considerable antiseptic power,[3] but it is but slightly astringent. Thus Fraser found that a solution of albumin rendered hazy by a 0·01 per cent. (1 in 10,000) solution of silver nitrate was not affected by a 3 per cent. solution of potassium bichromate. Nevertheless, it must not be forgotten that potassium bichromate is an acid salt with a slight acid reaction, and to this fact part of its pharmacological effect may be due. On the whole, I think we must include this salt under the head of gastric tonics or stomachics. The dose, as I have already indicated, is one-tenth of a grain (one-eighth to one-twelfth) on an empty stomach. It may be given in pill or in solution, with a flavouring agent, or, as I prefer, in capsules. Of contra-indications to its use I know none. Gergens produced nephritis experimentally (degeneration of renal epithelium, albumin, and tube casts in urine), but this only after large doses. Excitation, followed by depression of the nervous system, also occurs after large doses, but although potassium bichromate has been administered therapeutically for some time no such ill effects have been produced.

TREATMENT OF SUNBURN (ERYTHEMA SOLARE) DURING THE VOLUNTEER WEEK AT ALDERSHOT.

BY ALFRED EDDOWES, M.D., C.M. EDIN.,
PHYSICIAN TO THE WESTERN SKIN HOSPITAL.

LAST year's experience as surgeon in the largest Volunteer camp was sufficient to show me that the various methods of treatment adopted for this sometimes serious form of suffering were unsatisfactory, at least in bad cases. Consequently, I determined to go into camp again this year, specially arming myself with additional remedies which, from my knowledge of their usefulness in skin affections generally, seemed likely to prove of value in relieving a trouble which ranks second only in importance to sore-foot amongst the few drawbacks attending what forms one of the best possible holidays for a town man. Though the week in camp this year was neither sunny on the whole nor dusty, there were produced sufficiently numerous and severe cases of sore and swollen faces, necks and arms to test the relative merits of my remedies. Briefly stated, my conclusions were as follows:—

Digitized by Google

Slight cases may be easily relieved by spirit and powder or lead lotion, or, better still, by a mixture of the latter with lotio calaminæ co. (equal parts).

Cases with a tender but fairly dry surface.—For these contractile collodion containing about 5 per cent. of prepared calamine appeared to answer well. I added the powder in order to give the collodion a dull and flesh-coloured appearance and in the hope that perspiration would the more readily escape through it.

The worst cases.—1. Those of the face and neck obtained most relief from "epidermin"—an emulsion of wax which has somewhat recently been introduced into skin practice from Vienna and is probably already well known to some readers of THE LANCET. As the preparations of epidermin originally made for me soon became mouldy I had a small amount of salicylic acid added to it, and Messrs. Savory and Moore were kind enough, at my suggestion, to colour the remedy, which is ordinarily white, to agree very well with the normal colour of the skin. Before applying the compound the inflamed part was dried, when necessary, with cotton-wool or a towel. The remedy was then applied as rapidly, accurately and evenly as possible with a spatula, no attempt being made to obliterate small ridges, as they settle down during the process of drying. Though the wax sets fairly soon, it appears desirable that it should be applied some time before a hat is placed upon it or it is subjected to much friction. A film as thick as ordinary brown-paper or as butter is usually laid on bread is sufficient. Additions or patchings can be readily made at any time without disturbing the portions which have been found adhering well to the skin. The 0·5 per cent. which was the amount of salicylic acid added does not appear to irritate the already inflamed skin in the very least degree. Whether it assists in releasing pent-up serum in the blisters which frequently accompany the dermatitis is doubtful at present, but certainly blisters quickly disappear under the artificial covering formed by the dressing. 2. The swelling of arms, which is sometimes so acute and sharply circumscribed as to suggest at first glance the possibility of its being erysipelas, is rapidly curable by Unna's zinc-glue dressing with butter-cloth bandage—a dressing which, by the way, is greatly improved in appearance when dyed a true flesh colour and dabbed with cotton-wool of the same hue.

Crude and brief as my observations have necessarily been, they are worth publishing as the hot weather has probably not yet passed, and as other members of the profession, who may have better opportunities than I, may perhaps be induced to employ the above-mentioned remedies and record their results. Those who reside in London will well understand that it does not afford a good field for observation of sunburn.

"Nullaautem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare."—MORGAGNI *De Sed. et Caus. Morb.* Lib. iv. Proœmium.

MIDDLESEX HOSPITAL.

TWO CASES OF INDURATION OF THE ERECTILE STRUCTURES OF THE PENIS CAUSING RETENTION OF URINE.

(Under the care of Mr. HENRY MORRIS.)

THE literature on the subject of affections of the corpora cavernosa is not extensive and these two cases will therefore be read with care. The first case is probably the less interesting of the two, as it is apparently clear as regards its nature and causation, whilst the prognosis of such cases is good. The character of the deposit in the other case must remain uncertain; it appears to have differed from the conditions described by van Buren—i.e., a chronic inflammation slowly extending in patients over middle age—for in its progress it much resembled a malignant infiltration of the part and caused very much suffering. For the notes of the cases we are indebted to Mr. G. H. Berkeley, late house surgeon.

CASE 1. *Hæmatoma of the left corpus cavernosum from strain a cause of retention of urine.*—A man twenty-six years of age was admitted into the Broderip Ward of the Middlesex Hospital on Oct. 20th, 1893, with retention of urine of more than twenty hours' standing, and with a hard painful swelling extending along the left side of the root of the penis to the perineum. This was within the left crus and corpus cavernosum. He stated that four days before (Oct. 16th) he was helping to lift a very heavy wringing machine when it fell over, pulling him with it. To save himself he gave a sharp jerk sideways and felt a sudden violent pain just above the symphysis pubis. This pain passed away and he felt nothing more of it till the next day. He passed urine without difficulty, but it was "very high coloured." On the day after the strain (Oct. 17th) he felt a pain extending along his penis to the perineum, and on the 18th he suffered great pain when passing urine, and detected a swelling behind his scrotum and on the left side of his penis. The swelling increased, and with it he experienced increasing difficulty in micturating, the urine at length merely dribbling away from him; so he continued up to the time of his admission on the 20th. Mr. Morris passed a catheter and drew off about four pints of normal urine. Some little difficulty with the urine continued for a day or two, but passed off as the swelling in the perineum subsided under rest in bed. By Oct. 31st the swelling, though less, was more clearly defined and its anterior extremity had a pouched process. All pain had gone. By Nov. 7th the swelling had almost disappeared and he left the hospital practically well.

CASE 2. *Consolidation, in nodular form, of the corpora cavernosa and corpus spongiosum, resulting in painful and difficult micturition and occasional retention of urine; cause unknown; median perineal urethrotomy; insanity; death.*—A man aged forty years was admitted into the Broderip Ward of the Middlesex Hospital on Oct. 23rd, 1893, on account of difficulty in passing urine. He stated that, with the exception of gonorrhœa followed by gleet fourteen years before, to the best of his recollection, he had never had any illness. About two years previous to present illness he had some slight difficulty in passing urine, but nothing was done for this, and eventually it got right of itself. A week before admission to the hospital he again experienced difficulty in micturition, trying sometimes ten minutes before any urine came, and then it passed only drop by drop at first, and afterwards would flow in a very small stream. So it had continued with him since, and he has had also pain of a burning character in the penile urethra during micturition. On admission there was felt near the root of the penis a hard oval swelling about the size of a filbert, situated partly on the dorsal aspect and partly on the left side of the organ. It was not adherent to the skin, which moved freely over it, but seemed to be confined and fixed within the left corpus cavernosum. There was also a similar swelling, but of a more elongated shape and about one inch in length, on the under surface of the penis; it was very hard and tense and in close proximity to the urethra, which it in fact surrounded. It was here that the pain was felt on micturition. The urine had a specific gravity of 1020 and did not contain albumin, blood, pus, or sugar. On the following day Mr. Morris passed a No. 10 silver catheter without difficulty, but stated that he met with some little resistance in the penile portion of the urethra. The patient bled a little after the catheterisation, and next morning there were several patches of bloodstaining each the size of a shilling on the sheets. During the thirty hours afterwards he passed twelve ounces of urine; then the catheter was required and twenty-six ounces were withdrawn. A No. 10 olive-headed instrument was used and passed without difficulty. Again a little blood followed the use of the catheter, and again for a few hours afterwards he micturated more readily, but with pain; but then once more difficulty occurred, requiring the reintroduction of the instrument. On Oct. 28th a catheter was tied in and hot fomentations were applied over the indurated parts of the penis and urethra. The catheter *en demeure* set up some simple urethritis which required aseptic irrigation, but the instrument was retained and the discomfort of urinating was thereby removed, and the swellings seemed to become softer. During November various treatment was tried, but things remained much about the same. The nodules in the cavernous and spongy bodies were not appreciably altered, but micturition seemed easier, and so on

Digitized by Google

Nov. 29th the patient sought his discharge. It was noted on this day that "the nodules are just as hard and seem to be joining one another more than before." On Dec. 5th he was readmitted. He then stated that he had remained quite easy till Dec. 2nd, when he was again unable to pass urine, and he applied at the out-patient department about 6 P.M. Unsuccessful attempts to relieve him by catheters were then made, and as there was no vacant bed in the hospital he was sent to the University College Hospital. Here, after several unsuccessful efforts had been made, a No. 7 silver instrument was passed, after which he bled a good deal during the night and had to rise to micturate every hour or two during the next day, micturition being attended with great pain. As he had been discharged from the University College Hospital owing to want of beds he returned to the Middlesex Hospital and was admitted. It was at this time noted that "both corpora cavernosa are now infiltrated with hard nodules or masses which extend nearly the whole length from the glans penis to the rami of the pubes." The glans itself was painful and ulcerated, and the urethra was the seat of considerable smarting pain, but there was no discharge from it. Chordee now became a marked symptom, and pain on micturition continued. The urine was of a specific gravity of 1018 and was strongly acid; it contained a trace of albumin, but no blood, pus, or sugar. After four days in the hospital it was noticed that the glans penis was becoming gradually enlarged and hardened, and as time went on it threatened to slough. All kinds of remedies were tried—ice, ointments, and lotions locally, and iodide of potassium, mercury, colchicum, salicylate of sodium, and many other drugs internally. On Dec. 18th he was seen by the late Mr. Hulke in consultation with Mr. Morris, and it was decided to apply nitrate of mercury ointment to the indurated parts, and to continue perchloride of mercury and potassium iodide internally. On Dec. 29th, as the urethra was almost obliterated, the passing of urine attended with great pain, and the deposit, whatever it was, had infiltrated the whole of the erectile structures of the penis, it was decided to open the membranous urethra in order to give physiological rest to the fore part of the urethra with the hope that absorption of the deposit would take place, and that relief from the constantly recurring pain of micturition would be realised. In performing the boutonnière in the ordinary way the crura penis were seen to be greatly enlarged and looked and felt like cartilage. Very free hæmorrhage followed the incision of the floor of the urethra. A drainage-tube was introduced into the bladder from the perineum and about thirty ounces of urine were withdrawn. The tube was tied in and the wound was plugged and dressed with iodoform. Subsequently cocaine was frequently injected down the urethra to relieve the pain, which was almost constant. The penis was after, as well as before, the boutonnière always in a state of nearly complete erection, and the patient bitterly complained of the aching pain this caused. During the first fortnight of January, 1894, the condition became more aggravated; the glans penis assumed a greenish hue all over its dorsal surface; there were "stinging" pains in the penis, and such restlessness and excitement, especially at night, that a special attendant was required. On Jan. 17th the state of things was so bad, and becoming rapidly so much worse, that Mr. Morris was contemplating obtaining the patient's sanction to amputate the whole penis, and he did propose to him to make free incisions into the indurated parts, but the man refused any further operation. The drainage-tube was retained in his bladder, and the slough on the glans spread peripherally, but not much in depth. The smell of the discharge from it was very offensive, and the patient continued in great pain in spite of the administration of morphia and other anodynes. By Jan. 23rd his sleeplessness, excitement, and restlessness had so increased that he was unquestionably insane and had to be put into an isolation ward, and the next day he was transferred to the Marylebone Infirmary. There he died within a day or two of his removal, and on inquiry it was ascertained that, unfortunately for the complete understanding of this case, no post-mortem examination was made.

Remarks by Mr. HENRY MORRIS.—These two cases from their great rarity seem to be worthy of being placed on record in the Hospital Mirror of THE LANCET. Case 1 is one of intra-cavernous hæmorrhage resulting from a strain, and it is interesting on account of its causing painful micturition and afterwards complete retention of urine. This was doubtless due to the direct pressure upon and deflection of the course of the urethra which the blood extravasating into and stretching the corpus cavernosum produced. The condition cleared up after a short period of rest in bed and the occasional use of the catheter.

Case 2 was altogether of a different character, though there was much the same effect produced upon micturition. Neither simple nor gonorrhœal nor syphilitic inflammation, nor injury, gout, tubercle, nor gummata were the cause of this disease. Neither was it an instance of calcification of the sheath and septum of the corpora cavernosa, nor of the cicatricial contraction after inflammation or gummata. I do not know how to classify this case, and I do not know, in the absence of a microscopical examination of the deposit, to what change to assign it. Its course was more like multiple malignant neoplasms. The chief symptoms were the nodular masses, which gradually coalesced, and which at length resulted in a condition of priapism, or at any rate of chronic thickening and stiffening of the organ which resembled nearly complete erection. Associated with these physical changes in the organ were the pain in the penis and urethra, which became at last constant, and the difficulty in micturition. The superficial sloughing of the glans penis is also noteworthy. As to treatment nothing did the patient any good so far as diminishing the induration of the erectile tissues of the penis; the boutonnière relieved the bladder, but made no change otherwise. The pain in the penis, and the terrible mental distress, sleeplessness, and excitement remained unabated by it. I have no doubt that the insanity which supervened was the direct effect of these causes. In the absence of a post-mortem examination I offer no explanation of the cause of death, which took place after he had left my hands. Should a similar case, equally untractable to local and internal remedies, come under my care I should certainly propose to freely lay open the diseased parts, and, if necessary, amputate the penis at its connexions with the pubes.

ESSEX AND COLCHESTER GENERAL HOSPITAL.

A CASE OF ADENOMA SEBACEUM.

(Under the care of Mr. H. LAVER.)

THE disease of the skin described below by Dr. Coleman is undoubtedly a very rare one, as he observes. There have, however, been a few cases published in recent years by Balzer, Pringle, and Caspary. In Caspary's case the little tumours had developed after small-pox. Microscopical examination showed them to consist of a great number of sebaceous glands, closely packed in the deeper parts of the corium, the other structures of the skin being healthy.[1] For the notes of this case we are indebted to Dr. Percy Coleman, house surgeon.

The patient is a man twenty-seven years of age. He attended the hospital to be treated for an injury to his hand, but, his skin affection being noticed, he was admitted as an in-patient. He stated that he was about eight years of age when the disease first made its appearance on his face. It commenced on the face on both sides of the nose as "small pimples," so small that no attention was paid to them. These "pimples" then began to form round the angles of the mouth and on the upper lip and chin. The last parts to be attacked were the eyelids and forehead. His family history is good. Seven brothers and two sisters are alive and healthy. One brother died in infancy. There is no history of new growths or insanity in the family. He is a healthy-looking, well-nourished man with an eruption on most parts of the face. The growths vary in size from mere papules to nodules each as large as a split pea. At the sides of the nose the papules are so thickly packed that they run together and form an irregularly nodulated surface with no healthy skin between. Below the lower lip there is a narrow belt of the disease running parallel to the lip and about half-way between the margin of the lip and the lower border of the jaw. The skin over the inferior maxillæ, as far back as the angles of the jaw, is thickly studded with papules, but here they are discrete. On the nose there are only a few papules, but several of the larger nodules. A few papules are to be seen on the forehead

[1] Sajous' Annual of the Universal Medical Sciences, 1892, vol. i A 2.

Digitized by Google

and on the skin covering the mastoid processes of the temporal bones. The lesions themselves are reddish in colour, firm to the touch, and at first sight have some resemblance to acne, but they are evidently not inflammatory. One or two of the larger nodules show an attempt at pedunculation. Nothing like an orifice to the sebaceous gland can be detected on any of the little growths, even with a lens. There is a scanty sprinkling of comedones about the rest of the face. On stripping the patient it was found that the skin of the back exhibited several soft flaccid tumours, some one-fourth of an inch in length. These are evidently soft fibromata. In addition to these there were numerous flat growths—the largest as big round as a sixpenny-piece—of a pale-pink colour and having the appearance of multiple warts. The skin over the shoulders, both front and back, was similarly affected. Here also there were many growths looking like solitary warts of a pale pinkish tint. In the left infra-clavicular region there was a patch of skin about four inches square thickly studded with whitish elevations somewhat resembling milium, but quite solid. Each elevation was about the size of a millet-seed in circumference, but very slightly raised, being only just perceptible to the finger. This patch had existed ever since the patient was an infant. His mother told him that "a frog had spit upon him on that place and had left that mark." He merely complains of a slight itching when he gets over-heated or works in an atmosphere laden with dust.

Remarks by Dr. COLEMAN.—This disease is so rare that the case described above seemed to me to be worthy of a detailed description. Very little mention is made of it in any of the text-books on medicine and surgery in general use. Hilton Fagge's work on Medicine states that "the little tumours appear to undergo spontaneous involution." It seems probable that the patch above described as existing beneath the left clavicle is the seat of this change in the growths. One other case, in which the disease was limited to the face, has come under my notice. The patient was a female idiot seventeen years of age. The description given above of the facial appearance is almost equally applicable to her case. Mr. William Anderson, of St. Thomas's Hospital, has kindly examined the case and confirmed our diagnosis.

Reviews and Notices of Books.

Leçons de Chirurgie (La Pitié, 1893–94). Par le Dr. FÉLIX LEJARS. Paris: G. Masson. 1895. pp. 629.

CLINICAL lectures have a distinct function of their own. They serve to concentrate attention on a special subject in a manner which cannot be attempted in a systematic treatise, and their educational value is great. It is becoming more generally recognised that many clinical lectures are worthy the attention of an audience more extensive than that to which they were first delivered. In the volume before us are forty-seven clinical lectures on various departments of surgery, delivered by Dr. Lejars at La Pitié Hospital during the session 1893–94. The first seven lectures are devoted to general surgical pathology; 19 refer to the surgery of the limbs, 3 to the head and neck, 3 to the alimentary canal, 7 to the genito-urinary organs, and 8 deal with gynæcological subjects. The lectures are too numerous to be referred to individually, but some are of more striking interest than others. One of the lectures on surgical pathology deals with Thiersch's grafts (or Ollier-Thiersch grafts, as Dr. Lejars prefers to call them, as Ollier practised this method as early as 1871, while Thiersch published his first results in 1874); the results which have been obtained by this procedure in the hands of Dr. Lejars have been exceedingly satisfactory, and especially was this the case with "varicose ulcers" of the leg, even when the ulcer has been annular; he concurs with Thiersch in insisting on prolonged rest in bed after the operation in order to assure the vitality of the grafts. Another interesting lecture in the same section deals with the exostoses occurring in childhood, and a case is quoted from Heyman which is greatly in favour of their hereditary nature, a woman and five of her six children being affected with multiple exostoses. In a lecture on fracture of the clavicle Dr. Lejars is inclined to advocate suture in recent cases when the deformity is very great; a good account is given of the various methods of suturing this and other bones.

Forty-two cases of radical cure of hernia form the basis of a lecture on that subject, and much emphasis is laid on the importance of choosing the cases on which to operate. The results recorded are certainly good, but in many of them sufficient time had not elapsed to allow a definite statement as to their permanent cure to be made. Suprapubic cystotomy receives an extended notice, and three indications are given for its performance. It should be performed: (1) in cases of acute prostatitis with complete retention when attempts to pass a catheter have failed; (2) when micturition is painful and difficult, and catheterisation, though possible, is accompanied by much trouble and bleeding; and (3) when septic infection of the bladder has become well marked. The gynæcological lectures are of great interest, especially the one dealing with the operative treatment of suppuration in the Fallopian tube or ovary. A lecture on the surgical statistics of the hospital for the year fittingly concludes the volume.

It may safely be said that there is no lecture in the whole volume which is without interest to the surgeon. The illustrations, 128 in number, have been very neatly drawn and engraved, and serve to enhance the appearance of the text, the typographical excellence of which is very great.

Heart Inflammation in Children. By OCTAVIUS STURGES, M.D. Cantab., F.R.C.P. Lond., &c. London: John Bale and Sons. 1895.

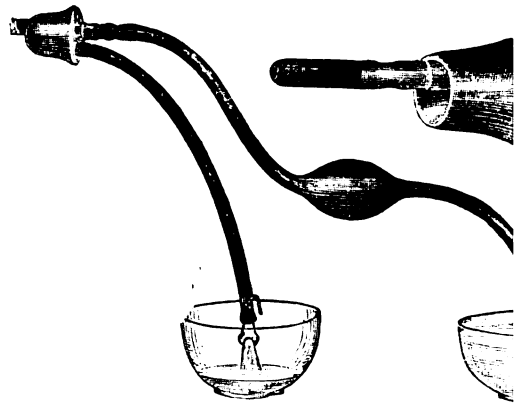
THE revision of this little book of eighty-two pages was the last work of the life of its lamented author. It is a reprint of the Lumleian Lectures delivered at the Royal College of Surgeons in 1894. It is also the ripe fruit of the mature and extensive experience of an observant and thoughtful physician too soon lost to his profession. Many much more pretentious monographs contain not a tithe of the value and guidance to be found in these pages, and to that large class who come more or less constantly in contact with ailing children we consider it our duty to recommend their perusal and reperusal. Apart from the valuable matter contained in the little work, there are an occasional felicity and sentiment in diction which indicate the cultured and sensitive gentleman, and which call for comment. "The heart of a little child, I say, at the first blush, would seem to be as simple in physical as it is in moral respects; but experience teaches otherwise. The child's heart holds as many secrets as the man's, and is even more deceiving" (p. 4). And again he quaintly remarks, in speaking of the friction rub of pericarditis as a diagnostic sign, "It may be said ..... of this sound, as of other things in Nature, that the noise it makes is not proportionate to its importance" (p. 22). There is a careful study of the pathology of cardiac inflammation, with good illustrations of the microscopic state of the muscle at various stages of the disease. The physical indications of this state are dealt with in the second lecture, and among other interesting points discussed the author enters in some detail into the question of the clinical recognisability of adherent pericardium, granting the possibility of diagnosing that "quite exceptional condition," costo-pericardial adhesion, when the pericardium is at the same time adherent to the heart (p. 40), but not that of "old adherent pericardium as we usually encounter it"—an opinion which the experience of most physicians will endorse. The author believed that extensive pericardial effusion, by tiding over the time during which the pericarditic surfaces were likely to adhere, had an

Digitized by Google

influence in obviating cardiac symphysis. Dr. Sturges was also one of those who was of opinion that the endocarditis of chorea was not necessarily rheumatic, and wisely criticises the tendency of extending the "idea" of rheumatism, which he likens to the eternal *noumenon* of ancient philosophy (p. 67), over too wide an area. There are many other points, alike in diagnosis, prognosis, and treatment, which the reader will find in this valuable guide to the subject with which the monograph deals, and which space forbids our particularising. Distinguished as the author was, and worthily so, he made perhaps less noise in the world than many less observant, less profound, and less reliable physicians, but in leaving to his profession the legacy of this masterly study of a very difficult subject he has laid those who survive him under a debt of gratitude, done much to perpetuate among us his memory, and in the length and interest of art to reconcile us to the brevity of life.

The Student's Text-book of Botany. By SIDNEY H. VINES, M.A., D.Sc., F.R.S. London: Swan Sonnenschein and Co. New York: Macmillan and Co. 1895. 15*s.*

THE name of Professor Vines is familiar to most students of botany in association with the well-known manual by "Prantle and Vines." In the work at present under consideration the author has to some extent followed the general arrangement of the older publication, but has made such extensive additions to all the sections that the book, besides retaining its special value for those commencing the subject, will now also serve as a useful guide to those who have gone beyond the elements of the science. The work is divided into four principal sections, which deal respectively with Morphology, Anatomy and Histology, Classification, and the General Physiology of Plants. The section on Classification occupies a large proportion of the book, and is based upon the natural fundamental relationship which exists between plants. This mode of classification, though necessarily at present incomplete owing to our deficiency of knowledge, is, as Professor Vines points out, superior to the more artificial methods, which must always be more or less arbitrary, the most successful of such artificial classifications being that of Linnæus, which is known as the "sexual system," and classifies the orders by the number and mode of arrangement of the floral organs. The last section of the book, which treats of the general physiology of plants, is very interesting, many of the chemical processes being fully given, and a table is drawn up to show the modes of income and expenditure both in those plants which possess chlorophyll and those which do not. The general physiology of reproduction is given, the laws of heredity and variation are touched upon, and there is an account of the various movements, automatic and otherwise, to which a plant is subject. The whole forms a very complete volume, which we have no doubt will be welcomed by those interested in the subject. The book is well illustrated and nicely bound.



Infant Feeding by Artificial Means: a Scientific and Practical Treatise on the Dietetics of Infancy. By S. H. SADLER. London: The Scientific Press, Limited. 1895.

THIS excellent manual is not only well stored with information necessary for mothers and nurses, but contains much that is of interest to the medical reader. The authoress has spared no pains in the collection of materials, and has consulted the best English and French authorities, quotations from their works being frequently given at considerable length. After some preliminary pages on the use of the feeding-bottle she describes the rearing of prematurely born infants by means of the "thermostatic nurse" or "couveuse" (a small wooden box warmed with hot-water tins), and the feeding of them with the œsophageal tube. Cow's milk is, of course, in most cases the staple sustenance of hand-reared infants. As it differs from human milk in having an exc of casein and a comparative deficiency of sugar, it l to be adapted to the digestion of infants by vari expedients, such as admixture with water, bar water, lime-water, tea, whey, and other diluents. may also be peptonised or partially digested with p creatic juice, and may be to some extent replaced the milk of the ass or goat. The authoress acknowledg preference for "artificial human milk," prepared by ad whey and milk sugar to cow's milk enriched with e cream. The formula for "artificial ass's milk" at p. will, perhaps, surprise her readers. Some more informa might have been given with respect to the sterilisatio Pasteurisation of cow's milk. The concluding secti devoted to various farinaceous proprietary foods, arrow raw meat juice, beef-tea, jellies, and puddings.

New Inventions.

THE "ZULA" SYRINGE AND IRRIGATOR.

THIS syringe has the advantage of being pr with a tube through which the fluid that has njected may flow away into the vessel intended to rece It therefore not only supplies a constant stream of flu vaginal injection, but avoids the usual annoyance of w or staining the underclothing or sheets during the a tion. The tube from the indiarubber ball leads into a vulcanite plug which completely closes the entrance

vagina and compels the surplus fluid to pass through opening in this plug, and so into the special outfl The ball with its injection tube may be readily detac the vaginal plug and fitted to an accompanying bo or rectum tube, and is then available for use as a syringe. The apparatus is made of enamelled blac and is packed in a box six inches by eight inches inches high. It may be obtained from any dr surgical instrument maker.

DEATH IN A HOSPITAL BATH.—A strang formed the subject of an inquest at Portsmouth on Aug. 29th. A man aged thirty-two was sent Newby as an applicant for admission to the Ro pital at Landport. He was suffering from bron both lungs, and, having been examined by the house was sent to get a bath and go to bed. The w from 90° to 100° F. in temperature, and on nurses asked him before he was left if he was s fainting fits, to which he replied in the negative. been in the bath-room about ten minutes when requiring something from the compartment, se to get it. The latter found Bunting (the under the water and at once ran for assistance. was, however, quite dead, and he had not the app asphyxia from drowning. A necropsy revealed a aneurysm.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 14, 1895.

THE British Association for the Advancement of Science held its sixty-fifth meeting this week at the ancient town of Ipswich, where it had assembled forty-four years ago. Ipswich, among other things, has a grammar school, where the renowned Dr. VALPY disciplined and taught the rising generation of his day, and where not so long ago a very notable Greek scholar of our time (Dr. H. HOLDEN) was the headmaster. It was at Ipswich, also, that HUXLEY first made the acquaintance of TYNDALL at the meeting of the Association in 1851. Sir DOUGLAS GALTON, K.C.B., D.C.L., F.R.S., the President of the Association, delivered the presidential address. The name of Sir DOUGLAS GALTON is a well-known one in scientific circles, and for many years past it has been associated with the advancement of sanitary science and the progressive development and practical advocacy of the principles of modern hygiene. He tells us that he first began to attend the meetings of the British Association about forty-six years ago, and that he was elected one of its general secretaries twenty-five years ago. It was both natural and fitting, therefore, that he should recall to the minds of his hearers the conditions under which science was pursued at the formation of the Association, the progress that has been made between 1831 and 1895, and the remarkable position which the Association has occupied in relation to science in this country. He made this consequently the text and pivot of his address. There was no lack of interesting and important material in the subject selected, and, indeed, it must have called for an exercise of the scientific judgment, and of the scientific imagination also, to know what not to say as well as what to say on the occasion. Sir DOUGLAS GALTON may be fairly congratulated, however, on having given his audience a very interesting and graphic account of the progressive steps in the march of modern science. We cannot, of course, traverse the whole field occupied in this presidential address—we can only follow a few of the furrows along which Sir DOUGLAS GALTON, in the orderly arrangement of his able review, disposed of his material, interspersing comments of his own which are generally conceived in a spirit of scientific faith in the future, although sometimes possibly in a too optimistic one. It has to be borne in mind that it is the main function of science to trace out the uniformities of sequence in all departments of nature, and the invariable consequences, within human experience, of certain antecedent conditions. The how and the why are mysteries that sometimes cannot be explained, but the work of science has been so fruitful of results that it always excites enthusiasm. Before passing to the more immediate subject of his address Sir DOUGLAS GALTON incidentally referred to the great loss which science has recently sustained by the death of the Right Hon. THOMAS HENRY HUXLEY. HUXLEY, he said, was pre-eminently qualified to assist in sweeping away the obstruction by dogmatic authority, which in the early days of the Association fettered progress in certain branches of science. For whilst he was an eminent leader in biological research, his intellectual power, his original and intrepid mind, his vigorous and masculine English made him a writer who explained the deepest subject with transparent clearness.

In 1831, when the British Association was founded, communication between different parts of the country was slow and difficult owing to the absence of railways. Science was, therefore, localised, and in addition to the universities in England, Scotland, and Ireland the towns of Birmingham, Manchester, Plymouth, and York each maintained an important nucleus of scientific research. In its origin the British Association invited the philosophical societies dispersed throughout Great Britain to unite in coöperative union, and within recent years it has endeavoured to consolidate that union. At the present time almost all important local scientific societies scattered throughout the country, some sixty-six in number, are in correspondence with the Association, which has, moreover, shown that its scope is conterminous with the British Empire by holding one of its annual meetings at Montreal, and it is likely soon, we are told, to hold a meeting in Toronto. Speaking of the condition of certain sciences at the formation of the British Association and of the enormous strides which have been made since 1831 in the investigation of facts to elucidate the laws of nature, Sir DOUGLAS GALTON adverted to the impediments offered to the progress of investigation by the mental condition of the community, which had been for so long satisfied to accept assumptions without undergoing the labour of testing their truth by ascertaining the real facts, and he furnished two illustrations of this habit of mind selected from the early reports of the Association. The whole habit of mind of the population of the Western world has been changed, he added, since the beginning of the century from willing acceptance of authority as a rule of life to a universal spirit of inquiry and experimental investigation; and he conjecturally asked whether this rapid change may not have arisen from society having been stirred to its foundations by the causes and consequences of the French Revolution, and proceeded to trace out this idea in connexion with the origin of the conviction that the basis of scientific research lay in the accuracy of the standards by which observations could be compared and the principles that were laid down as a basis for their measurements of length, weight, and capacity. Sir DOUGLAS GALTON followed up and illustrated his suggestive inquiry in various interesting directions. Passing over such subjects as our progress in geological and geographical science, chemistry, astronomy, and physics, we may, nevertheless, parenthetically allude to the force and *verve* embodied in that section of his address devoted to the consideration of the progress we have made in the sciences which are included under physics. The late Professor ROMANES held that no reason can be assigned why God should not be immanent in nature or why all causation should not be the immediate expression of His will; and, speaking of

Digitized by Google

the probable close connexion of electricity with the vibrations which cause heat and light and which seem to pervade all space, Sir DOUGLAS GALTON, with an exercise of his scientific imagination, remarked: "Vibrations which may be termed the voice of the Creator calling to each atom and to each cell of protoplasm to fall into its ordained position, each, as it were, a musical note in the harmonious symphony which we call the universe." Under the head of animal physiology allusion was made to CUVIER, who died in 1832, Sir RICHARD OWEN, and DARWIN, and to the non-acceptance by OWEN of the latter's theory of evolution—a doctrine now generally accepted, but on the threshold of which we are still standing as it were, and concerning which each fresh investigation suggests fresh problems. Evolution, as Sir WILLIAM FLOWER said, is the message which biology has sent to help us on with some of the problems of human life, and so Sir DOUGLAS GALTON had a good deal to say about anthropology in relation to heredity, psychology, and the science of preventive medicine. His address also gave a brief but excellent sketch of the origin, progress, and relations of the modern science of bacteriology to our knowledge of life, health, and disease, forming a point of meeting, as he said, where the biologist, the chemist, the physicist, and the statistician unite with the sanitary engineer in the application of the science of preventive medicine.

As might have been expected, Sir DOUGLAS GALTON condensed much useful information in his remarks on sewage purification, and spoke with the authority that comes of knowledge in dealing with the scientific principles which should guide us in this respect. He concluded his address with some pertinent and forcible observations on the relations of science to the State and the way in which our Governments have so largely profited by science, and remarked upon the small measure of recognition in the way of honours that have been conferred by the State upon leaders of science as compared with those awarded to its own officials, to the army and navy, and to politicians. He considered that Government assistance to science in other respects might also be more pronounced than is the case.

As might have been anticipated at this season there has been a revitalisation or recrudescence of cholera, but happily not on any large scale, at various places abroad where the epidemic had already prevailed in past years. According to official returns from St. Petersburg over 2000 cases of cholera, with 718 deaths, occurred in the government of Volhynia between July 11th and Aug. 17th. The town of Vladivostock has been declared infected with the disease, and so has the province of Podolia. Some cases have also occurred in Galicia and in districts adjoining the Russian frontier. There has been a sharp outbreak of cholera at Tangier, and communication between that place and Gibraltar and Malta has been stopped in consequence. We learn from San Francisco that the disease has been recently prevailing at Honolulu, and that the United States Consul at that place warned the captain of an American-Australian Line steamer of the fact in view of none of the passengers being landed. No further news has arrived from Japan of the extensive epidemic outbreak of cholera in that country to which we alluded last week. The disease in this case followed the Chino-Japanese war and the increased communication between Corea and Japan. But cholera is said to be raging in China, a large number of deaths occurring daily at Pekin. There was a remarkable decrease in the amount of cholera in India last year, but it was unusually prevalent in Burma, where no fewer than 7428 deaths were recorded, which was very largely in excess of the mortality of the previous year from this cause.

As regards this country the alleged reappearance of cholera on the Humber and the reported occurrence of two suspicious cases at Grimsby, both of which terminated fatally, gave rise to some apprehension. This feeling was very natural under the circumstances, especially as it was stated that cases of diarrhœa had been exceptionally prevalent of late in Grimsby and Hull. The Medical Department of the Local Government Board despatched one of their inspectors to inquire into the facts and ascertain the local conditions of the Humber ports. But the results of Professor KLEIN'S bacteriological observations have happily not been corroborative of the fears that were entertained that the cases in question were those of Asiatic cholera. The failure to discover the comma bacillus, on the one hand, and the non-extension of the disease in the locality, on the other, show that the cases at Grimsby were in all probability only those of so-called English cholera, such as might be expected to arise at this season from ordinary causes, and they do not consequently at all justify the belief that there is any recrudescence of the late epidemic at Grimsby. Bearing in mind the period of the year which we have now reached, the hot and dry autumn we are enjoying, and our freedom from any manifestations of a cholera epidemic in this country up to the present time, we are not inclined to be apprehensive of the extension to this country of the epidemic which has marched from the East and prevailed with such force in Russia and other countries on the continent of Europe.

As we have already intimated, the natural life-history of an epidemic usually covers a period of from three to four years. We have still much to learn as to the time during which the cholera-cause or pathogenetic micro-organism may remain dormant or latent, but still capable of renewing the manifestations of its vitality under the operation of favouring conditions. It is clear that a good deal will depend upon several circumstances, some of which are of an apparently insignificant, but really of an important and influential, character in determining the renewed activity or recrudescence of the disease. If we may judge from what we know of cholera in the past one thing seems to be fairly well established—viz., that there may be recurrences of outbreaks in a locality without any fresh reimportation of its cause. Whether we regard the bodies of the sick as the exclusive sources of the development and multiplication of the cholera-cause, or look rather, as some do, to the environment for an explanation of these phenomena, it seems clear that the infecting cause may long remain dormant, and that the environment is an important factor in the history of cholera, otherwise removal from an infected locality would not be attended with

Digitized by Google

the results which experience has shown to be the case. Although we have not by any means yet attained a perfect hygienic standard, the sanitary state of our cities, towns, and rural districts is altogether superior to that of most places abroad. We are aware of our defects and keenly alive to the importance of keeping our systems of water-supply protected from all contamination, and, thanks to the sanitary surveillance exercised by the Medical Department of the Local Government Board and our port sanitary authorities we are promptly made acquainted with any sources of danger and infection from without and have adopted a simple, practical, and, to judge by the results of our experience during the recent epidemic, an apparently successful method of dealing with them, simply because those methods are such as commend themselves to the intelligence and common sense of the community at large and are practicable in their application.

OUR readers no doubt have read the accounts of the recent pilgrimages to Lourdes and the marvellous cures alleged to have been effected at the shrine of the Virgin in the little Pyrenean village. The story of the arrival of trains laden with sick folk, the vast processions of the lame, the halt, and the blind, the imposing ecclesiastical ceremonies, and the alleged miraculous recoveries seems to take us back to the Middle Ages, and it requires an effort to convince ourselves that all this is really going on in free-thinking France and in the nineteenth century. But France has no monopoly of the modern miracle. It is not long since the little village of Knock in the West of Ireland was the scene of pilgrimages on the part of sick people, and when even the plaster from the walls of the shrine there was held by the faithful to possess the most magical healing powers. And now another case reaches us from St. Winifride's Well at Holywell. A retired soldier forty-two years of age, alleged to be suffering from "heart disease, diseased bloodvessels in the leg, and to be of a consumptive tendency"—a fairly comprehensive, if not very exact or convincing, diagnosis—was brought to the well by an attendant (the patient being a cripple) and lifted into the water. He stated that he felt "as if he had electric batteries at work all over him," and after a time said that he thought he could stand. He did so and was able to move freely about to the astonishment of all present, as only a short time previously he had come to the place on crutches. On the same afternoon he was seen walking comfortably about the streets and apparently well. The correspondent who describes the incident concludes by saying that "the cure is generally regarded as one of the most extraordinary that have yet taken place at the well." We give the facts as they have appeared in the lay press. This case is, of course, in no way exceptional and belongs to the numerous class whose thank-offerings of votive legs, arms, eyes, &c. presented at the various shrines are among the most familiar objects of Continental travel.

There are three possible attitudes which may be assumed towards these alleged miracles of healing. There is the attitude of the pious believer, who accepts these stories on the authority of his ecclesiastical superiors, whose faith is to a large extent independent of evidence and to whom the essential point is not scientific accuracy but pious edification. We need hardly say that with this class we have no direct concern, and we are by no means disposed to insult the convictions of those who differ widely from ourselves. There is a second class who take the view that these alleged cures are all absolute frauds, a mere playing by cunning men upon the superstitions, frailties, and misfortunes of the ignorant multitude. We do not regard this position as by any means wholly satisfactory, or one that can be easily reconciled with the facts of the case. We think a third view, intermediate in character, more tenable. We think it probable that many of the prominent leaders in these scenes act quite *bonâ fide*. That actual "cures" take place is by no means incredible. They have been repeatedly attested by men whose *bona fides* is incontestable and whose incapacity for making a correct observation is by no means to be lightly assumed. Having said so much by way of admission, we must add that we have seen no evidence that in the least degree inclines us to admit any supernatural or miraculous element in these cases. Probably these alleged cures are capable of differentiation and are not to be readily grouped under one heading. Putting aside cases of imaginary ailments and of conscious or unconscious imposition—and we are entirely of the opinion that these two classes are largely represented at most shrines of healing—let us assume that there remain a considerable number of cases in which definite maladies have disappeared after recourse to these shrines or sacred wells. It by no means follows that a miracle has been wrought, though by pious and ignorant observers this seems the natural, the inevitable deduction. The question first arises whether any of these sacred waters—it is to be observed that a spring or a well is an almost invariable, certainly a very frequent, adjunct of these shrines of healing—might possibly possess some real therapeutic virtues. There is nothing improbable in such a supposition. The electric bath is a therapeutic agent of considerable potency. A bath in water surcharged with carbonic acid gas exercises an influence over the organism, and especially upon the nervous system, which may in certain subjects produce surprising results. How far certain of these so-called miraculous springs and wells may possess qualities analogous to these we cannot say, but there is nothing extravagant in the supposition that such analogies may exist.

But we must frankly confess that we have a strong conviction that the great majority of these "cures" belong to a wholly different class; that they are, in fact, identical with those neurotic cases with which hypnotism has made us so familiar. It will always be observed in reading the accounts of the phenomena alleged to occur at Lourdes, Knock, and elsewhere that the cures occur precisely in the sort of patient and in forms of disease most likely to be affected by forces identical with, or analogous to, hypnotism. Highly strung, enthusiastic, and visionary girls figure largely in these accounts, while the diseases alleged to be most amenable to cure are such affections as catalepsy, paralysis, blindness, &c., all of which occur frequently as functional affections liable at any moment to be dissipated by any cause that makes a strong impression on the nervous system. No doubt cures of such conditions as advanced phthisis have been repeatedly alleged, but, so far as we know, a careful investigation by competent persons has

Digitized by Google

always disproved the genuineness of such cases. Often the marked temporary improvement has been merely the result of an extreme exaltation of the nervous system, to be quickly followed by a resumption of all the old symptoms and the inevitable end. It is not our business to touch on questions of a theological nature—e.g., such as the possibility of miracles or the like. We may leave such subjects to the professed theologian or to his assailants. But we are much concerned in anything that vitally touches the science of medicine or the art of healing, and therefore we need make no apology for offering these observations to our readers. While not denying all reality to these curious phenomena it must always be a pathetic sight to see multitudes of suffering men and women turning away from the well-proved methods of scientific medicine and following strange paths which in the vast majority of cases can conduct to nothing but disappointment and death.

Annotations.

"Ne quid nimis."

MEDICAL ADVERTISING IN AUSTRIA.

THE members of the Vienna Medical Chamber have recently been engaged in the consideration of professional advertising, the main point at issue being the fixation of limits beyond which the practice should be prohibited. After a lengthened and animated discussion the following articles were adopted. A medical man committing any of the acts hereafter specified shall be considered guilty of an offence against professional dignity: 1. Causing, or permitting, or refraining from preventing (when he has the power) the insertion of advertisements in newspapers, journals, indexes, guide-books, annuals, leaflets, circulars, or any other description of printed matter. This article, however, does not refer to medical publications, nor is it meant to hinder a medical man from publicly proclaiming his entry into practice, his return after a prolonged absence, or his change of domicile, provided the notification is not repeated more than three times. The same information may also be conveyed by means of a circular, but in both cases the notice must contain nothing additional beyond the name of the advertiser, his academical qualifications and legal medical designation, an indication of the speciality he professes, his address, and the hours he is at home for consultation. 2. Publishing, or allowing to be published, letters of thanks and expressions of gratitude from patients who have been treated by him. 3. Recommending, either directly or indirectly, in pamphlets and popular publications, his own system and methods of treatment in preference to those of other practitioners. 4. Allowing commission to midwives, waiters, commissionaires, porters, &c., in return for their services in procuring him patients. 5. Drawing public attention to himself by means of a charlatan's sign-board. 6. Endeavouring in an unbecoming manner, after the fashion of quacks, to attract notice to the medical establishment he either owns or directs. From the foregoing it is evident that far more latitude in the way of advertising is allowed to the medical profession in Austria than is the case with us. We are certainly of opinion that the best way to safeguard professional dignity is by drawing up a hard and fast regulation prohibitive of personal announcements of every kind and description. Half measures are never productive of good. We sincerely hope that the permission to insert professional advertisements in the lay press, no matter how severe the limitations, may never become acclimatised in England. In order to show how liable a concession is to abuse it is only necessary to mention the inordinate growth of practitioners' door-plates in Paris. Originally, as with us, simple rectangular pieces of brass, bearing the name of the practitioner in letters of modest dimensions, they have now, according to M. le Baron, developed into gigantic sign-boards affixed in many cases to windows or even to balconies.

THE EXAMINATION FOR THE DIPLOMA OF PUBLIC HEALTH (ENGLISH CONJOINT BOARD).

A "PROSPECTIVE M. O. H." writes protesting against the present mode of conducting the examination for the above-named diploma, which, he says, "bids fair to the establishing of an unsurmountable barrier to any general practitioner ever again hoping to obtain it." The unsuccessful candidate is apt to attribute his failure to the fact that he did not manage to satisfy the examiners concerning his knowledge of some few technical points, when possibly it may have been rather a general lack of information with regard to the subject matter of examination which proved his ruin. In the present instance the papers of a "Prospective M. O. H." are not in evidence, but, taking him upon his own ground, the case he makes out is far from being a strong one. He objects to being expected to understand the mechanism of the Bramah press, and complains of being questioned concerning the influence of climate, damp, and soil on acute rheumatism. He says the differential diagnosis of a scarlet-fever rash is a "purely medical question," and should not be made the subject of examination for a public-health diploma. The practical part of the examination consisted, he tells us, of "rushing the candidates round some sewage works," and requiring them to write a paper on sewage. The fact is, he concludes, that the whole system of examination as at present conducted is "rotten to the core." The line of argument of a "Prospective M.O.H." is far from being convincing, and the instances he cites do not appear to tell in his favour.

THE LATE MILITARY MARCH.

As might have been anticipated, numerous reasons have been assigned in explanation of the fact that a large number of soldiers fell out during the late march from Aldershot to the New Forest. That there was a sudden accession of heat, which was great while it lasted, and that the force was largely composed of young soldiers, who were unequal and comparatively unaccustomed to the physical strain and fatigue of carrying their arms and equipment on long marches through dusty roads in sultry weather, everybody admits. That the men showed a good deal of pluck under the circumstances, and that many of them, footsore and distressed, nevertheless manfully struggled on, is not denied. Practically speaking, there is no good in dwelling upon the fact that young soldiers cannot sustain heat, fatigue, and weight-carrying as well as those who are older and more matured and better trained. We must take our soldiers when we can get them—that is, when they are young. The men are good enough if only time be given them to develop and to be physically trained for military exercises and marches. The British army has always given a good account of itself in the field, and, after all, we are no worse off under a short service system than are Continental nations in this respect; but we have to meet requirements in regard to foreign service—in India and the colonies—such as do not fall to the lot of other nations. The question arises whether nothing can be done in the way of better adjusting our systems of military dress and equipment to the soldier's occupation and the varying seasons and circumstances in

Digitized by Google

which he is placed. A great many years ago an article appeared in *Blackwood's Magazine* entitled "How shall we dress him?"—to which a practical reply still remains to be given. We have no doubt vastly improved upon the system in vogue at the time of the Crimean War and for some years subsequently, but we have not yet attained our object. The marching power, other things being equal, will, for example, greatly depend upon the way in which the soldier is shod. A good deal has, no doubt, been done in this direction, but the ammunition boot is not perfect—it is too heavy and inelastic, for hot weather especially. This is not to be wondered at, considering the irritation and distress which we all of us more or less undergo at the hands of our bootmakers in civil life. The Metropolitan Police Force are a splendid body of men, but they cannot run fast. The dress of a sailor of the Royal Navy contrasts very favourably with that of the soldier in regard to ease and freedom of movement. As to weight-carrying, the recruit or young soldier wants to have his kit carried for him on a long march until his body and limbs become developed and he has been fitted by a gradual process of training to carry it for himself. The return march of the troops was a much more satisfactory performance. To provide a suitable dress for different seasons of the year is, of course, a matter of difficulty and grave expense where a large army is concerned.

OVER-ZEAL.

MR. HANKIN, the official bacteriologist at Agra, is said to have had a narrow escape from death from cholera through being too confident in the powers of his disinfecting drugs. Mr. Hankin has been for some time engaged in the special investigation of cholera, and has devoted a great deal of attention to the disinfection of the drinking water in the wells, and after various experiments finds potassium permanganate to give the best results. In many cases after the well water had been thus disinfected cholera ceased in the immediate neighbourhood supplied by the well. In one instance, however, Mr. Hankin, anxious to impress the natives with the efficacy of these measures, is said to have himself drunk some water from the well very shortly after the potassium permanganate had been put in. The result was, as might have been expected, an attack of cholera, which, however, proved to be a mild one and terminated favourably. While Mr. Hankin deserves all thanks for his important researches and his devotion to his work, we cannot think that any such experiments on himself as the one above described are justifiable. The world cannot afford to lose valuable lives by experiments which can only prove dangerous to the operator and are not in any way directly the means of saving other lives.

SCARLET FEVER IN BIRMINGHAM.

THE sanitary officials of Birmingham have for some time past been kept actively engaged in their efforts to cope with an ever-increasing epidemic prevalence of scarlet fever in that city. It is true that the prevailing malady is of a mild character, the deaths registered in the three last weeks of August having been only 3, 4, and 5 respectively, and only a single death was registered in the first week of the present month; but the cases newly arising from week to week have been in increasing amount, and August has witnessed a larger total of attacks than did July, though the deaths have been almost identical in number. Great encouragement is felt in the much more frequent recognition of hospital treatment on the part of parents, as beneficial in comparison with home treatment of patients, the percentage of removals to attacks being some 80, so that the hospital register can now be looked upon as containing by far the larger proportion of total cases coming to light. And it is just this register which goes to show the rapid growth of scarlet fever this year in Birmingham over its incidence in 1894. Twelve months ago the highest number in hospital was 239, and the number gradually sank until in February last it had declined to 170, rising again to 200 in the succeeding two months, with a further increase to 240 by the end of May and up to 260 in June. In July the cases coming to the knowledge of the health department showed the disease to be rife in all parts of the city, patients being received into hospital from all quarters, and the beds occupied numbering 340, whilst towards the close of last month the cases under treatment were as many as 460 in number, being nearly double the total of any day in August of last year. The sanitary authority has not, however, lost heart, and Dr. A. Hill is looking hopefully for a steady decline now that what he regards as the maximum epidemicity has been reached. We sincerely trust it will shortly be manifest that the worst is over.

THE ADULTERATION ACTS.

A NICE point of law arose last week in a case in which a provision dealer was summoned before the Wigan County Justices charged with two offences under the Margarine Act, 1887—viz., that he had exposed margarine for sale without a distinguishing label being attached to it, and also that he had sold it as butter. The defendant pleaded guilty. An inspector employed by the Royal Lancashire Agricultural Society visited the defendant's shop and saw *round pounds* of butter exposed for sale in the window. He purchased a pound and then told the defendant who he was, whereupon the defendant admitted it was margarine. The inspector did not tell the defendant he was going to have it analysed, and did not offer him a portion in order that he might have it analysed because he admitted it was margarine. The assistant magistrate's clerk advised that owing to this omission the bench could not deal with the case. The prosecuting solicitor said as the defendant had pleaded guilty the bench had power to convict, but this was overruled. Here we have a case in which the defendant pleads guilty, and yet escapes the penalty because the inspector omits what appears to be a technical compliance with the provisions of the Act.

MADAGASCAR.

THE news brought each succeeding day from Madagascar regarding the health and sanitary state of the French expeditionary force in that country is more and more unsatisfactory. The engineering corps and those of the troops who have been engaged in road-making have suffered greatly—as we had indicated they probably would—from the effects of malarial disease due to soil emanations and from exposure to the heat and climatic influences. About 40 per cent. of the force are said to be inefficient or in hospital suffering from fever, dysentery, and other diseases, and there has been a heavy list of mortality and invaliding. The hospitals must, indeed, be full to overcrowding according to the descriptions of them afforded by correspondents. The low-lying districts are especially hot and unhealthy, and of the soldiers still in the field it is stated that a large number of them are suffering from malarial anæmia, footsoreness, and swollen feet. The fighting casualties have been insignificant; the real enemies have been heat and malaria and the difficulties of transport and food supplies for the force. The special correspondent of the *Débats* gives a somewhat gloomy description of the expedition. The march from Mojanga to Suberbieville was across a very hot and unhealthy country, and a great deal of the sickness is ascribed to it and to the construction of a road for the waggon transport. This correspondent also finds

Digitized by Google

fault with the hospital arrangements and insufficient number of medical officers and sick attendants, but this seems to be mainly accounted for by the amount of sickness among them. The French troops are generally too young for the work and unacclimatised. A feeling of discontent prevails in the expeditionary force, and the news from Madagascar is likely to cause great disappointment in France and prove a source of trouble for its Government. It seems surprising that the French War Office were not better informed as to the climatic and local conditions that would have to be encountered in Madagascar before undertaking the expedition. It is impossible not to have some misgivings as to the future, but we sincerely hope to hear better news when the force succeeds in reaching Antananarivo.

FACIAL HEMIATROPHY AFTER INFLUENZA.

A CURIOUS case of facial atrophy is briefly related in the *Neurologisches Centralblatt* in an abstract of a paper by Dr. Berend in *Orvosi Hetilap*. A girl aged twelve suffered from a severe attack of influenza two years ago, and a few weeks later had sharp pains in the face. The parents soon noticed a wasting of one side, and when she came under observation it was found that the hair on the left side of the head was thinner and the skin wasted as low as the corner of the mouth. Below this level the opposite side of the face was affected in a similar way. The changes were most marked in the skin and the subcutaneous tissues, but the bones also showed distinct changes. Dr. Berend refers the changes to an affection of the first and second divisions of the nerve on the left side, and to a similar affection of the third branch on the right side.

MICROBES ON MONEY.

THE *Revue d'Hygiène* publishes an interesting account of some experiments made at the bacteriological laboratory of the Military Hospital of Dey at Algiers. Dr. H. Vincent explains that money is specially liable to be contaminated by saliva, pus, pathological secretions, dust, and the morbid germs that may be found in dirty pockets or on dirty fingers. He does not think, however, that evidence of this danger can be easily obtained by placing dirty coins in culture broth. The investigations at the Dey Hospital were conducted in a different manner. A piece of cotton-wool about the size of a pea was dipped in water and sterilised. Pieces of wool thus prepared were seized with pincers that had been held in a flame and were gently passed over the coin to be examined. The pieces of wool were then placed in culture broths and kept in a temperature of 35° C. The product, which soon contained various micro-organisms, was sown anew in gelatine plaques so as to isolate the bacteria. In other cases it was inoculated in doses varying from one to five cubic centimetres in the blood or under the skin of rabbits, guinea-pigs, and white rats. A lengthy description of the methods employed and the results obtained is given. The number of bacteria found on the surface of coins varied very considerably—on silver and gold from 460 to 3500, and on copper a still larger number. To destroy many of the non-pathogenic microbes some experiments were made at a temperature of 37° C. The injection of mixed cultures from coins only produced death or serious results in about one out of every ten inoculations. Death was sometimes rapid, with symptoms of acute septicæmia. In one case tuberculosis was communicated to a rabbit by a piece of wool which had been passed over a ten-centime copper coin. In another case there was slight tetanus. There can be no doubt that germs of disease are often to be found on the surface of coins—notably the microbe of suppuration, the staphylococcus pyogenes, and the streptococcus. Nevertheless, as the experiments were repeated they proved that there were fewer infectious germs than had been anticipated. Another series of experiments was then made which demonstrated that though coins are often contaminated they possess in themselves antiseptic qualities which greatly reduce the risk. If pathogenic germs are placed on coins it is seen that they do not live long. The time varies according to the temperature and the nature of the metal. In a cold temperature the germs of typhoid fever and the Friedlander bacillus are killed in eighteen hours if placed on a sterilised copper or silver coin; and the pyocyanic bacillus and that of green diarrhœa in twenty-four hours. At a temperature of a pocket, about 36° C., the bacilli of typhoid fever, of blue pus, of diphtheria, and the streptococcus are destroyed in less than six hours. The bacilli of diphtheria are among the most tenacious, and in cold will live three days on silver and six days on bronze. Gold, of course, is less antiseptic, and the Eberth bacilli will live five days and that of diphtheria six days on a gold coin in a temperature of 20° C. At a damp temperature of 36° C. the destruction of the microbes is very rapid, and that is the temperature which often prevails in the pockets of clothes. It is some consolation to find that the danger, when it exists, is not one of long duration; still, there is time enough, even in six hours, for much mischief to be accomplished. It is, therefore, the moral duty of all who are suffering from infectious disease to refrain from handling pieces of money.

THE BRITISH DENTAL ASSOCIATION.

THE annual gathering of this association was held at Edinburgh on Aug. 29th, 30th, and 31st, and proved to be most successful. The new President, Mr. Bowman Macleod, delivered a most interesting address and strongly advocated the establishment at our leading institutions of a chair in Clinical Dental Surgery. A large number of papers were contributed, that by Dr. Frederic Hewitt on Chloroform in Dental Surgery creating most interest. The writer's facts were clearly put, and his statistics of the number of deaths under anæsthetics in dental surgery tended to show that the death-rate runs a long way the highest in Scotland, where the use of chloroform is so prevalent. The paper gave rise to a valuable discussion, Dr. W. H. Williamson trying ably to defend the administration of chloroform in Scotland. The demonstrations were given at the Edinburgh Dental School and proved as attractive as usual. At the Microscopical Section several communications and papers were brought forward, including a most valuable one from Professor Hunter on the subject of photomicrography, and the system shown and advocated produces the very best results without the aid of the expensive objectives that are in general use. The association will hold their meeting next year in London during the month of August.

FILTERS IN INDIA.

WE have for a long time past persistently urged on the Government of India the importance of adopting the Pasteur-Chamberland or the Berkefeldt filter in substitution of that in ordinary barrack-room use in Indian cantonments, which is not only inefficacious, but under certain circumstances a source of positive danger to the troops. Mr. Hankin, the Government Bacteriologist of the North-Western Provinces of India, in addition to other excellent work which he has done for his own Government and that of India generally, has shown as the result of his experiments and observations that the filter in ordinary use allows the passage of starch grains, the diameter of which, it is needless to add, far exceeds that of the comma bacillus or other micro-organisms. But experiment shows that some of the cholera microbes nevertheless remain behind in the filter, where they go on breeding. In

Digitized by Google

the case of the late outbreak of cholera in the East Lancashire Regiment at Lucknow, for example, it was proved to the satisfaction of the commission of investigation into its causes that the exacerbation of the outbreak among the troops who had been moved into camp was attributable to infected filters having been removed from the cholera-infected barracks to camp. Mr. Hankin states that under certain conditions traces of the cholera microbe will even pass through the Pasteur-Chamberland or Berkefeldt filters, although he has reasons for thinking that this will not detract from their practical utility. Why should not experimental trials be made of these filters at several selected stations in India where enteric fever is unduly prevalent? It should not, surely, be difficult to devise a number of experimental trials in order to determine whether their employment was followed or not by a cessation or diminished prevalence of the disease.

THE LATE MR. DURHAM.

WE have received the following appeal from the Treasurer of Guy's Hospital:—"Dear Sir,—We are sure that the friends of the late Mr. Arthur Edward Durham would desire that steps should be taken to perpetuate his memory in association with Guy's Hospital, to which he devoted the best years of his life and work. The particular form which such a memorial should take has been a matter of careful consideration, and with the full assent and approval of his family it has been decided that at the present time, when the finances of the hospital are so seriously embarrassed, the best tribute which can be paid to his memory is the endowment in perpetuity of two beds, one in each of his old wards, Lazarus and Martha, to be called the Arthur Durham Beds. For this purpose a sum of £2000 will be requisite. In appealing to his old friends and admirers for liberal subscriptions towards this worthy object it is needless for us to dwell upon the manifold services Mr. Durham rendered to Guy's as a teacher and surgeon of the first rank, upon the unaffected kindness of his disposition, and upon those genial traits of character which endeared him to all who had the privilege of knowing him. Contributions should be paid to Mr. C. H. Wells, at the Office of the Medical School, and they will be acknowledged from time to time in the *Guy's Hospital Gazette*. In the belief that many will be glad to possess such a memento, it is proposed to present subscribers of one guinea and upwards with a platinotype enlargement of what is regarded as the most life-like photograph of Mr. Durham, in a form suitable for framing.—We are, dear Sir, yours faithfully, E. H. LUSHINGTON, Treasurer; P. H. PYE-SMITH, Senior Physician; H. G. HOWSE, Senior Surgeon."

THE BORDEAUX CONGRESSES.

IF only congresses and contentment were always united the city of Bordeaux should be simply brimming over with complacency. Taking advantage of the fact that an exhibition was in progress, the representatives of no fewer than seven erudite associations decided to hold their annual reunions in the sunny capital of South-western France; and the consequence was that during the early days of August the banks of the Garonne were thronged with learned men of well-nigh every European nationality. As Dr. E. Masse has it in his weekly bulletin:[1]—"Our town of Bordeaux can never congratulate itself sufficiently on having had the honour of affording hospitality to such a large number of *savants*, of physicians, and of surgeons, who came together from all the points of the universe—Russians, Belgians, Spaniards, Portuguese, Swiss, Italians, Bulgarians, Roumanians, Greeks, all have comported themselves with honour at the diverse congresses." England alone seems to have been unrepresented; English names are conspicuous by their absence from the various records of the proceedings, and yet the subjects dealt with were both opportune and interesting, as may be seen by the following list of titles: Geography, Protection of Infant Life, the Latin Tongues, Alienism and Neurology, the Advancement of Science, Medicine, Gynæcology, and Obstetrics. Inasmuch as four, if not five, of these congresses were concerned with matters appertaining to the science and art of medicine the absence of representatives belonging to this country is much to be regretted; but doubtless the abstention was owing to the coincidence of the British Medical Association meeting in London. Be this as it may, there can be no question that a holiday amidst the vines of Gironde would have been highly enjoyable. Notwithstanding the plethora of congresses the entire time of the 3000 visitors was by no means exclusively devoted to business. On the contrary, the majority of them contrived to find ample leisure for amusement, and the way a lengthy programme of fêtes, banquets, and excursions was done justice to clearly shows that the Continental disciples of science know how to give effect to the old Horatian maxim by a judicious admixture of the useful and the agreeable.

[1] Gazette Hebdomadaire des Sciences Médicales, Aug. 11th.

OCCUPATIONS FOR WOMEN.

THE *Woman's Signal* notices that in one portion of the daily press women's energies are directed towards weddings and in another towards burials. Our contemporary then says: "Ought not THE LANCET to follow with an intermediary suggestion?" As far as we can see there is no need for our interference. The intermediary state between weddings and funerals is birth, and women can and do attend at this function only too frequently as it is. We always fail to see the force of the constant cry of new occupations for women—there is nothing they do not do nowadays from literature to massage. We ourselves have seen in Armenia a woman ploughing—we mean drawing a plough,—the remainder of the team being made up of a donkey and a camel. It should be mentioned that the woman was not an Armenian, but a Tatar, and although this occupation may appear unfeminine it would seem far more hygienic and no less fitting an employment for women than much of our factory labour. To come nearer home, however, we know of a metropolitan mortuary where the assistant at post-mortem examinations is a woman, and, as far as handicraft goes, she is a most excellent and handy helper. If this employment is open to women, surely the emancipation of the sex is complete. While on the subject of post-mortem examinations in public mortuaries we wish to call attention to the fact, as we believe, that the medical man making the examination has to provide his own post-mortem instruments. This, it seems to us, is wrong. Every vestry should provide a set of its own for use in cases which are examined at the mortuary. They are not expensive and could be easily kept in order by the mortuary keeper.

UNIVERSITY STATISTICS IN SWITZERLAND.

"A HOLIDAY CONTRIBUTOR" writes under date Zürich, Aug. 28th:—"Following up your recent annotation giving the university statistics of Switzerland for the winter *semestre* of 1894–95, I have been favoured with the official return of the same for the summer *semestre* of 1895. The seven Swiss seats of learning during this half-year have numbered 3108 students, of whom 47 were ladies, and 634 amateurs, of whom 144 were ladies. The total is 3742 (191 ladies), or 71 (9 ladies) fewer than the preceding half-year. The distribution of students and amateurs into faculties is as follows: Theology, 440 (274 Protestants and 166 Catholics); law, 648 (5 ladies all at Zürich); medicine,

Digitized by Google

938 (200 ladies); and philosophy (science and literature), 1656 (286 ladies). Of the 3108 students properly so called 1774 are Swiss (42 ladies); Germany furnishes 504 students 51 ladies); Russia, 348 (199 ladies); Bulgaria, 131 (10) ladies); France, 56 (2 ladies); Austria, 53 (9 ladies); Roumania, 49 (9 ladies); Turkey, 39 (8 ladies); Italy, 36; and North America, 32 (7 ladies). The University of Zürich counts the greatest number of students properly so called (673 of whom 125 are ladies); Geneva comes next with 665 students (117 ladies). If, however, to the students we add the amateurs, Geneva leads the van with 824, of whom 176 are ladies; Zürich follows with 752 students and amateurs (158 ladies); Berne, 649 (96 ladies); Bâle, 609 (5 ladies); Lausanne, 493 (44 ladies); Fribourg, 308; and, finally, Neuchâtel, 107 (12 ladies). Fribourg and Bâle, as in the previous half-year, count the greatest number of theological students (161 in the former and 81 in the latter). Lausanne numbers most in the faculty of law (her 125 have risen to 161), while Berne falls from 150 to 147. Medicine always counts most students at Zürich (331) and at Geneva (274). The latter has 376 students and amateurs in science and literature and Zürich 347."

INTOXICATION BY CHLORALOSE.

DR. HERZEN describes a case of this kind in the *Revue Médicale de la Suisse Romande*. The patient was suffering from phthisis and twenty centigrammes of chloralose were administered. An hour later he became collapsed—pale, unconscious, covered with sweat, and with a flickering and very rapid pulse. Every fifteen or thirty seconds he had convulsive movements of the extremities and of the muscles of mastication. Ether was administered subcutaneously and after two hours the contractions ceased, and in four hours the patient had recovered. Dr. Herzen says that his patient was used to morphia and chloral, and the very profound effects produced by a medium dose of the drug suggest that a considerable amount of care should be used in its administration.

THE DIFFUSION OF SMALL-POX.

THE deaths from small-pox in London in the last week of August were 4 in number, and occurred in as many different sanitary areas in the East-end. During August 14 deaths were ascribed to this disease in London, as compared with 6 in the previous month. Last week the deaths registered were 5 in number, 2 belonging to Camberwell and 1 each to Islington, Whitechapel, and Plumstead sanitary areas. Of the 9 deaths thus occurring in the last fortnight 3 were in vaccinated adults, 2 in unvaccinated, and 1 in vaccinated young children, and concerning the remaining 3 (all of whom were adults) there is no statement as to their vaccination. The new attacks recorded in the fortnight were 37 and 36 respectively, and the admissions to hospital 36 and 25. As before, the southern and eastern groups of districts suffered in much greater proportion than the western and northern sections of the metropolis. The cases remaining under treatment in hospital had been gradually increasing from 19 on June 15th to 357 on August 24th; but on Sunday, Sept. 1st, a decline to 333 was shown, 196 cases being accommodated at Gore Farm, 135 on the hospital ships, and 2 at the South Wharf. On Saturday last a further decline to 328 was recorded. A few attacks are stated to have occurred recently in West Ham. In the Midlands an outbreak, limited at present to the members of one family, has been discovered at Loughborough, and two of the patients have been removed to hospital; the third case, though the small-pox was apparently mild, proved fatal from syncope. In Boston workhouse a tramp fell ill with small-pox three weeks ago, and this case has been followed by 4 others in that institution; all of them were removed to the fever hospital, and upwards of a hundred inmates of the workhouse were vaccinated. In the last week of August a fatal case was registered in Preston, and another in Oldham, in which latter town some half-dozen attacks are reported to have come to light. Last week there was another death in Oldham, and one in Manchester, where 5 attacks were heard of. In Dublin a continued decline was manifested in the week ended Aug. 24th, only 3 admissions to hospital being reported, against 10 discharges, and in the succeeding week 3 admissions, against 6 discharges, only 15 acute cases being left in hospital on the last day of August, as compared with 28 three weeks earlier.

POISONOUS LITERATURE AND ITS ANTIDOTES.

SOME day, perhaps, the law may interfere directly with the publication and sale of sensational literature; as yet the prohibitory line has not been drawn or even described with the accuracy required for legal definition. We may, at all events, be thankful that some countenance is given by the Statute-book to the view that sheer immorality of expression is incompatible with social order. In times when the frank and open condemnation of indecent practices is treated by many as a mere prudery, a Puritanic affectation, this is something to be thankful for. We would fain hope that those legal authorities who in this country represent the *censor morum* will before long find means of analysing the penny dreadful, and of including it within their poisons' act. As an aid in the same work, though far too little used, we have already the great force of education. This weapon, indeed, has a double edge. By conferring the power to read it has opened a road to every mind for the widely distributed germs of morbid fancy. It is bound by public duty to provide a remedy, and we have in the meantime no agent so reliable as it may easily become for the purpose of mental disinfection and invigoration. It is to its powerful influence, whether employed by a parent or a teacher—and a duty is incumbent upon both in this connexion—that we must chiefly trust in order to attain this purpose. To forbid what is pernicious is not sufficient. Parents and teachers alike must go further and seek frequent occasion out of school or in school not only to expose the idle and mischievous tendency of the cheap horrors of publication, but to substitute for these equally light and attractive but wholesome reading. There is plenty of such material in circulation, but much of the best is still somewhat expensive. We would only add a hope that more of it may be brought out in penny editions.

HOW FEVER IS SPREAD.

IT is vain to expect that all our precautions to arrest the spread of infection will be effectual unless they be assisted by the loyal coöperation of private persons. The importance of this fact cannot be too strongly insisted on. In a matter of this kind our neighbour's interest is our own, and if it is not so regarded the effect of our selfish unconcern may at any time recoil upon ourselves. No rightly thinking person can, therefore, find fault with a decision given last week in the Thames Police-court against a woman who in removing from her home conveyed her son (who was suffering from scarlet fever) in a tramcar. Such cases are not known to be of frequent occurrence, though we suspect that a certain unknown proportion of them successfully run the gauntlet and escape detection. The observant care of medical men, of sanitary inspectors, and of the non-professional but most deeply interested community at large cannot be employed with too much zeal in this direction. It appears to us, moreover, that less than enough is now done to render the transit of infected persons convenient and safe. When we come to look into the subject there is practically only one means to this end which is of general utility—namely, the hospital ambulance. Obviously, too, this method

Digitized by Google

is itself seriously hampered by restrictions. It is part of the service of a special institution, and is not readily available in emergencies for which that service is not directly responsible. A few cabs are kept by some owners for ambulance purposes, but so few that their existence might almost be ignored. Railway companies make no special provision for the fever-stricken. Yet everyone can appreciate the dilemma which confronts an invalid so smitten and his friends when illness overtakes him in a seaside or country lodging, with home accessible if only he were not infectious, and perhaps no hospital either near or suitable to his condition. The whole question is worthy of consideration by those who have to do with organising our means of transit, and if a satisfactory solution could be arrived at the working efficiency of the Public Health Act would be thereby increased.

ALLEGED CHOLERA RECURRENCES.

WE are glad to state that, although there has been another death of an adult from "diarrhœa" in Great Grimsby and more than one suspicious attack, there is as yet no bacteriological evidence of a recrudescence of cholera, and we hope there will be none. Great Grimsby has by no means a clean record as to autumnal diarrhœa; but it is unusual to find adults succumbing to even severe attacks of that disease. We would therefore urge on the town council the utmost vigilance at this critical season, especially in view of the history of Great Grimsby during the present European cholera epidemic.

DIPHTHERIA IN LONDON.

THE decided diminution in the number of deaths from diphtheria in London, shown by the Registrar-General's returns to have occurred in the third complete week of August, was, unhappily, not maintained in either of the last two weeks, the number of deaths registered in the week ended Saturday, Aug. 31st, having risen from 24 to 40, a total which was 11 in excess of the corrected average for the corresponding week of the preceding decennial period, whilst in the week ended Sept. 7th the registered deaths were 38—that is, 9 above the average. The patients remaining under treatment in hospital on Saturday last amounted to 662, and have not diminished in number. The preponderance of deaths among children is once more manifested, and with the recent reopening of schools in London it seems hardly likely that a decline of the disease will now take place. In the two months just ended there were in the nine registration weeks 416 deaths from diphtheria in London alone, yielding a weekly average of 46; and some slight consolation may be derived from the fact that this average was in excess of the deaths recorded during the last half of August as well as during the first week of the present month. In West Ham registration district, which is extra-metropolitan, 6 deaths occurred in the concluding week of August, and 9 during last week.

THE minutes of evidence which the Select Committee on Food Products Adulteration have been able so far to take are contained in a Blue-book published this week. The volume consists of 462 pages and deals for the most part with that very important and perhaps most interesting section of the inquiry—viz., the evidence and views of traders and manufacturers. Even in a rapid glance through the numbered paragraphs we have alighted upon not a few statements of the "startling revelation" order, but these and other points we propose to discuss at some length in a future issue.

Two deaths from hydrophobia have been recently reported, one from Rochdale, and the other from Preston.

WE regret to say that Sir Douglas Galton, during his delivery of the presidential address (referred to in our leading columns) before the British Association at Ipswich, was seized with sudden illness, which prevented him from reading the concluding portions of the address. We are glad to be able to state that he recovered sufficiently to acknowledge a vote of thanks.

WE regret to announce that Dr. Ruffer will not be able to deliver the course of lectures, as advertised, at the British Institute of Preventive Medicine, as he is suffering from an attack of diphtheritic paralysis and will not be able to do any work for some time.

THE fortune of the late Mr. Charles Mitchell, LL.D., is estimated at £1,800,000, and it is stated authoritatively that no further public benefactions are announced. Owing to his death the Aberdeen celebrations have been postponed till December.

Pharmacology and Therapeutics.

YEAST IN DIABETES.

DR. CASSAËT finds that a couple of ounces of yeast taken at meal-times are very useful in diabetes. At first the yeast tends to cause eructations and even diarrhœa, but after a few days the system tolerates it perfectly well, and the patient finds his appetite improved, his pains less, and his general condition better than before commencing the yeast. Even in a case where phthisis was present and there had been considerable loss of weight there was a gain of several pounds at the end of a fortnight, and the dynamometer showed an increase in muscular power. The amount of sugar in the urine decreased, in one case from 32 to 7½ parts in 1000. This yeast treatment of diabetes is not new—indeed, there are few remedies which have not been at one time or another employed in this affection. Dr. Herepath recommended it as long ago as 1854, and Dr. Oppolzer again employed it in 1868.

BROMIDE OF LITHIUM IN BRIGHT'S DISEASE.

A Russian physician, Dr. Polakoff, has found bromide of lithium of great service in Bright's disease, both in acute and chronic forms. He has employed it in twenty-two cases and finds that it acts as a certain and powerful diuretic, diminishing the quantity of albumin in the urine and frequently causing the œdema to disappear entirely. The patients were not kept on milk diet, but were allowed to eat ordinary food, and no other drugs were given at the same time nor any baths. The effect appeared to be more marked in acute than in chronic nephritis. The albuminuria began to decrease after a short period of treatment, on the thirteenth day at the latest, the diminution continued up to a certain point, and then the amount of albumin became stationary; but if the salt was stopped for a few days and then recommenced it was found possible to obtain a further decrease in the albumin. In one of the cases—that of a woman with puerperal convulsions—the attacks, which had resisted baths, morphia, and even chloroform, disappeared after a single day's treatment with bromide of lithium. As a rule the drug was well borne, but in two of the patients it produced nausea and vomiting and had to be stopped for a time. In one case of acute nephritis, too, hæmaturia was produced, which, however, rapidly ceased on the drug being discontinued and some tannin being given. The mixture ordered consisted of 1½ to 2 parts of bromide of lithium and 4 parts of bicarbonate of soda in 240 parts of distilled water flavoured with peppermint. Of this three or four tablespoonfuls were ordered per diem.

SUCCINATE OF AMMONIA IN LABOUR.

According to Dr. Remy of Nancy, succinate of ammonia is very useful in spasmodic cramp-like pains and in partial contraction of the internal os during parturition. In a case where this contraction occurred during the third stage of labour, rendering it impossible to deliver the placenta, a couple of doses of the above-named remedy relaxed the spasmodic condition and enabled the after-birth to come

Digitized by Google

away without difficulty. The mixture recommended is a simple solution of the succinate in 140 times its weight of water, a tablespoonful dose being given every quarter of an hour until relief is obtained.

PRIZEMEN AND MEDALLISTS AT THE METROPOLITAN MEDICAL SCHOOLS.

St. Bartholomew's Hospital and College. — Lawrence Scholarship and Gold Medal: J. K. Murphy. Brackenbury Medical Scholarship: S. Gillies. Brackenbury Surgical Scholarship: L. Giles. Matthews Duncan Medal and Prize: T. S. Pigg. Senior Scholarship in Anatomy, Physiology, and Chemistry: E. C. Morland. Open Scholarships in Science, Chemistry, and Physics: A. L. Ormerod. Biology and Physiology: W. L. Brown; Junior, F. C. Borrow and S. R. Scott (equal). Preliminary Scientific Exhibition: L. A. Walker. Jeaffreson Exhibition: C. A. S. Ridout. Kirkes Scholarship and Gold Medal: not awarded. Bentley Prize (medical): E. W. Groves. Hichens Prize: not awarded. Wix Prize: C. C. I. Turnbull. Harvey Prize: H. Davies. Sir George Burrow's Prize: not awarded. Skynner Prize: T. J. Horder. Practical Anatomy, Junior (Treasurer's Prize): F. C. Borrow, W. H. Leonard, and S. R. Scott (equal), H. Burrows, A. R. Baker, C. S. Frost, H. S. Thomas, E. Wethered, C. R. Brown, and L. A. Walker. Practical Anatomy, Senior (Foster Prize): R. Raines (Prize), E. C. Morland, L. A. Baiss, and G. E. Gask (equal), A. O. B. Wroughton, W. T. Rowe, S. A. Millen, H. E. Waller, H. D. Everington, and F. Horridge. Shuter Scholarship: not awarded. Junior Scholarships: (1) S. R. Scott, (2) F. C. Borrow, and H. G. Wood-Hill (equal). Junior Scholarship in Chemistry, 1894: H. A. Colwell and E. C. Morland (equal).

Charing Cross Hospital Medical School.—Pereira Prize: F. P. Jones. Governors' Clinical Gold Medal: D. C. Rees. Anatomy Prize (Junior): C. B. Wagstaff. Biology Prize: C. B. Wagstaff. Chemistry Prize: J. E. Humphreys. Physiology Prize (Senior): W. E. Morgan. Physiology Prize (Junior): W. H. Unwin. Practical Physiology Prize: W. E. Morgan. Medicine Prize: W. C. Bosanquet. Surgery Prize: C. Hudson. Practical Medicine Prize: W. C. Bosanquet.

Guy's Hospital.—The Treasurer's Gold Medal for Clinical Medicine: Francis J. Steward. The Treasurer's Gold Medal for Clinical Surgery: Francis J. Steward. Gurney Hoare Prize for Clinical Study: Arthur H. Leete. Beaney Prize for Pathology: Francis J. Steward. Sands Cox Scholarship for Physiology: George E. Richmond, prize £15. Michael Harris Prize for Anatomy: Frederick E. Walker, prize £10. The Arthur Durham Prizes for Dissection—First Year's Students: John T. M. M'Dougall, prize £5; Second Year's Students: Frederick E. Walker, prize £15. The Hilton Prize for Dissection: John O. Garland. Third Year's Prizes: Robert P. Rowlands, prize £25; Robert Howard, second prize, £10. Second Year's Prizes (1894): Edmund I. Spriggs and Robert P. Rowlands (equal). Dental Student (1895): Joseph L. Payne, prize £15. First Year's Prizes (1894): Philip Turner, first prize, £50; George E. Richmond, second prize, £25. Dental Students (1895): Kenneth W. Goadby and Norris Snell (equal), £5 each. Practical Dentistry Prize: Edward C. Dimock, prize £10. Open Scholarships in Arts: Arthur Pearson, £100; George William Hare, £50. Dental Student: Guy Chatterton, £30. Open Scholarships in Science: Thomas F. Rutter, £150; John T. Dunston, £60.

St. George's Hospital.—Brackenbury Prizes (Medicine): Sidney Smith. (Surgery): F. Morley. Treasurer's Prize (the gift of his Grace the Duke of Westminster): Walwyn Thomas. Certificate of Honour: E. T. Fison. Brodie Prize: R. A. Cooper. Henry Charles Johnson Prize (Anatomy): H. L. Barwell. Pollock Prize (Physiology): R. E. Drake-Brockman. First Year's General Proficiency Prize: T. M. Neatby. Honorary Certificates: F. Paul, H. G. Drake-Brockman, A. Morley, and Lawrence Pick. Second Year's General Proficiency Prize: H. L. Barwell. Third Year's General Proficiency (Honorary Certificates): H. M. Vernon, J. W. Watson, and H. P. Foulerton. William Brown Exhibition of £100 per annum, tenable for two years: Walwyn Thomas. Entrance Scholarship (October, 1894) of £145: T. M. Neatby. University Scholarships of £85: J. T. Watson, B.A., St. Peter's College, Cambridge, and J. E. Kirk, B.A., Christ's College, Cambridge.

King's College.—Warneford Scholarship: Class I., W. L. Stuart and A. T. Marshall for three years; A. C. Williams for two years. Class II., M. S. Mayou. Rabbeth Scholarship: F. C. Carle and W. L. Stuart (equal). Senior Scholarship: J. M'D. Troup and G. H. Lansdown (equal). Second Year Scholarship: T. H. Gardner. Junior Scholarship: W. H. M'Mullen, C. A. Sprawson, and A. Brown. Sambrooke Exhibitions: C. A. Sprawson and A. Brown. Clothworkers' Exhibition: R. W. H. Bailey and C. F. Mott. Warneford Prize: R. P. Williams. Divinity: Barry Prize, A. T. Marshall; prize, A. D. Reid. Anatomy: J. C. Briscoe. Physiology: J. C Briscoe. Chemistry: J. C. Briscoe. Botany: R. H. Gompertz. Medicine: J. M'D. Troup. Clinical Surgery: A. H. Burt. Surgery: G. H. Lansdown. Tanner Prize: G. H. Lansdown and W. B. Bell (equal). Forensic Medicine: R. P. Williams. Obstetric Medicine: W. B. Bell. Materia Medica: A. Brown. Todd Clinical (Medical): A. H. Burt. Pathological Anatomy: J. M. Schaub. Hygiene: J. M. Schaub.

The London Hospital Medical College.—Price Scholarship in Science, £120: W. R. Dunstan. Price Scholarship in Anatomy and Physiology, £60: H. W. L. Barlow. Entrance Science Scholarships: £60, H. D. Pollard; £35, R. Howard. Buxton Scholarships: Arts, £30, T. Chetwood; £20, J. S. Dudding. Clinical Medicine: £20 scholarship, Elgar Down. Clinical Surgery: £20 scholarship, H. F. Tod. Clinical Obstetrics: £20 scholarship, E. Maynard. Duckworth Nelson Prize: £10, Elgar Down. Letheby Prizes: Senior, £20, L. C. Lander; Junior, £10, G. S. Ward. Sutton Scholarship, £20: E. Mallam. Anatomy and Physiology: £25 scholarship, I. W. W. Hunter and T. S. Novis (equal). Anatomy and Biology: £20 scholarship, A. F. Tredgold. Dressers' Prizes: C. Pike, C. W. Chaplin, J. M. Garman, and A. Orme (equal); I. W. W. Hunter, H. G. Frankling, S. Gaster, and G. H. Herbert (equal).

St. Mary's Hospital.—Entrance Scholarships in Natural Science: 100 guineas, J. J. Pierce; 50 guineas, C. W. Buckley; and 50 guineas, W. A. Trumper. University Scholarships of 50 guineas: A. A. Bathe, M.A., and A. Graham Butler, B.A. Exhibition in Natural Science: 25 guineas, H. J. Van Praagh. Summer Session, 1894.—Prizes. Third Year: Practical Surgery, A. Stanley. Second Year: Midwifery, W. Ashdowne; Medical Jurisprudence, J. E. P. Davies. First Year: Materia Medica, A. Howell; Practical Chemistry, A. F. Hayden; Chemistry, H. T. Mann. Winter Session, 1894-95.—Third Year: Medicine, A. W. Sanders; Surgery, A. W. Sanders; Pathology, R. H. Steen, B.A., and A. H. L. Newstead, B.A. Second Year: Physiology, F. S. Dawe; Histology, R. C. Leaning. First Year: Anatomy, A. Von Rosen; Physiology, W. B. Watson. Third and Fourth Years: Prize in Ophthalmology of £10 10*s.*, R. Percy Smallwood, B.A., and Basil Pares; Prize in Dermatology of £5 5*s.*, H. H. G. Knapp, B.A., and J. O. Skevington; Clinical Surgery, 1894, R. W. Dodgson; Clinical Medicine, 1894, R. W. Dodgson. Special prizes, 1894, for general proficiency in Anatomy and Physiology (including Histology), A. Howell; for general proficiency in Medicine and Surgery (including Operative Surgery), Mr. A. Stanley; Prosectors, R. C. Leaning and S. M. Smith.

Middlesex Hospital Medical School.—Broderip Scholarships: J. C. K. Braine-Hartnell and E. D. Aubin. Hetley Clinical Prize: N. B. Harman. Governor's Prize: F. C. B. Gittings. Murray Scholarship and Medal: F. C. B. Gittings. Lyell Medal: H. P. Noble. Exhibition, Second Year: G. H. Lucas. Exhibition, First Year: A. J. Knowlton and W. A. S. Lamborn (equal). Entrance Scholarships: E. H. M'Enery and A. J. Knowlton. University: G. H. M'Cleary. Class Prizes—Medicine: E. D. Aubin. Surgery: E. D. Aubin. Practical Surgery: C. Roberts. Practical Midwifery: E. D. Aubin and E. K. Herring (equal). Anatomy: A. E. Relph. Physiology: A. E. Relph. Chemistry: W. A. S. Lamborn and C. T. Baxter. Biology: H. Hipwell. Dissections: F. H. Lawson. Practical Medicine: H. E. Wise. Pathological Anatomy: A. E. Walter. Obstetric Medicine: C. Roberts. Practical Physiology: F. F. Elwes. Pharmacology and Therapeutics: C. Roberts. Psychology: J. T. Wills. Practical Pharmacy: C. G. Pugh.

St. Thomas's Hospital.—Entrance Science Scholarships: J. Gaff, first scholarship, £150, and certificate of honour; H. R. Beale, scholarship, £60, and certificate of honour; H. Calvert, exhibition of £20 and certificate of honour. University Scholarship: W. M'Dougall, scholarship, £50,

Digitized by Google

and certificate of honour. First Year's Students: J. Gaff, the William Tite Scholarship, £27 10*s*., and certificate of honour; H. R. Beale, College Prize, £20, and certificate of honour; H. Calvert, College Prize, £10, and certificate of honour. Second Year's Students: H. E. Hewitt, the Musgrove Scholarship, £38 10*s*., and certificate of honour; R. W. C. Pierce, College Prize, £20, and certificate of honour; H. D. Singer, College Prize, £10, and certificate of honour. Third Year's Students: A. W. Sikes, College Prize, £20, and second tenure of Peacock Scholarship, and certificate of honour. Practical Medicine: F. B. Thornton, the Mead Medal founded by Mr. and Mrs. Newman Smith; P. S. Hitchens, certificate of honour. Surgery and Surgical Anatomy: B. Dyball, the Cheselden Medal, founded by the late George Vaughan; A. J. Martineau, a Bronze Medal. Pathology and Morbid Anatomy: A. L. Home, the Bristowe Medal. For General Proficiency and Good Conduct: A. J. Martineau, the Treasurer's Gold Medal.

University College, London: Faculty of Medicine.—Entrance Exhibition (£57 15*s*.): H. Hawker. Atchison Scholarship (£55 per annum for two years): J. H. Cook. Atkinson-Morley Scholarship (£45 per annum for three years): A. Dimsey. Cluff Memorial Prize (£15): Charles Bolton. Bruce Medal: J. H. Cook. Pathology and Morbid Anatomy (Tuke Silver Medal): Charles Bolton; (Tuke Bronze Medal): H. J. Price. Surgery (Gold Medal): J. H. Cook. Physiology (Theoretical and Practical) Senior Class (Gold Medal): Campbell Dykes; Junior Class (Silver Medal): H. Hawker. Anatomy (Senior Class) (Silver Medals): Montague Dixon and A. Martin-Leake (equal); Junior Class (Silver Medal): J. E. Simpson. Medicine (Gold Medal): J. H. Cook; Silver, A. Dimsey; H. J. Price and H. B. Shaw (equal). Practical Surgery (Erichsen Prize): H. B. Shaw. Clinical Medicine (Senior Class) (Fellowes Gold Medal): T. H. C. Stevenson; Fellowes Silver Medals: A. Dimsey, A. J. Rodocanachi, and E. W. M. Westcott (equal); Junior Class (Fellowes Silver Medal): C. Bolton. Clinical Dental Surgery (Silver Medals): C. C. Clarkson and A. Dimsey (equal).

Westminster Hospital Medical School.—Entrance Scholarships (October): G. E. Cope (£60) and S. Dodd (£40). Oxford and Cambridge Entrance Scholarship: F. R. King (£40). Entrance Scholarship (May): G. H. Auchmuty (£40). Treasurer's Prize for First Winter Subjects (prize): Lewis Cook (10 guineas). President's Prize for Second Winter Subjects (prize): E. B. Sherlock (20 guineas). Class Prize Medicine: R. H. F. Towne and F. Riley (equal). Class Prize Surgery: F. Riley. Clinical Surgery: R. H. F. Towne. Clinical Medicine: G. F. S. Genge. Bird Prize and Medal: R. H. Norman (£14). Chadwick Prize: A. J. Smith (£21). Physics: F. W. W. Dawson. Practical Chemistry: G. E. Cope. Histology: W. A. Durance. Pathology: A. E. Jerman.

London School of Medicine for Women. — Physiology (prize): Miss Leete. Biology (prize): Hon. Ella Scarlett. Anatomy first year (prize): Miss Clapham. Anatomy, second year (prize): Miss Hawker. Organic Chemistry, 1893-4 (prize): Miss Garrett Anderson. Organic Chemistry, 1894-95 (prize) Miss Hawker. Medicine (prize): Miss Despard. Surgery (prize): Miss Hull. Operative Midwifery (Prize of £5 5*s*. given by Mr. Wood): Miss E. G. Adams. Summer Session, 1895.—Materia Medica (prize) Miss Carr and Miss Sharman (equal). Practical Organic Chemistry (prize) Miss Iles. Practical Histology (prize): Miss Castledine. Pathology (prize) Miss Mabel Webb. Forensic Medicine (prize): Miss Hull.

The London School of Dental Surgery.—Saunders Scholar, W. H. Pidgeon; Ashs' Prize, F. J. Padgett. Winter Session, 1894-95.—Dental Mechanics: First Prize, W. H. Pidgeon; Second Prize, H. K. Jeffes. Metallurgy: First Prize, G. Fisher; Second Prize, H. K. Jeffes. Operative Dental Surgery: First Prize, W. H. Pidgeon; Second Prize, W. Marston. Summer Session, 1895.—Dental Anatomy: First Prize, H. Dunlop. Dental Surgery: First Prize, F. J. Padgett; Second Prize, H. Dunlop. Students' Society Prize: F. J. Padgett and H. W. Turner.

PROFESSOR LIONEL BEALE, F.R.S., F.R.C.P.Lond., proposes to give a lecture on the Foundation of Medical Science, introductory to his part of the course on the Principles and Practice of Medicine, in King's College, London, on Friday, Oct. 4th, at 4 P.M.

THE BRITISH DENTAL ASSOCIATION IN EDINBURGH.

THE annual meeting of the British Dental Association was held in Edinburgh on Aug. 29th, 30th, and 31st. The meetings were held in the University, the necessary rooms being willingly granted for the purpose. There was a large display by various firms of apparatus and materials used in dental work, these being accommodated in the examination hall and in the practical zoology class-room. The exhibits were tastefully displayed and attracted much attention. The proceedings commenced with a meeting of the representative board, which sat beyond its advertised time and thus delayed for some time the general meeting, which was advertised for 10.30 A.M.

In the absence of Mr. C. S. TOMES (London), the President of the Association, the chair was occupied by Mr. J. SMITH TURNER (London), vice-president. He referred to the family bereavement which had prevented Mr. Tomes from being present, and read a short valedictory address which Mr. Tomes had prepared. He (Mr. Tomes) thought that during the past year a little real progress had been made in many directions. In the administration of the Dentists Act they had succeeded in prosecutions which had broken fresh ground, and so had crippled fresh forms of evasion which had hitherto been untouched. One form of attempt to evade the Act was for the intending offender to constitute himself into a bogus or "one-man" company. A departmental committee was appointed by the Board of Trade to inquire into and suggest amendments to the existing Companies Act, and this committee had been so far influenced by the facts laid before it by various bodies that they introduced into their draft Bill a clause which, if it became law, as it probably would, would enable complainers to have any company formed for a fraudulent or illegal purpose compulsorily wound up, and the Court might in such a case declare the liability of any or all of the members to be unlimited. With reference to the additions to the literature of the profession, Mr. Hopewell Smith's "Handbook of Dental Histology" was commended as a book which every dentist should have beside him. He also referred to papers by Dr. Black of Jacksonville, in which he had determined the force exerted in ordinary mastication, and had shown that that exercised by an artificial denture fell far short of that exercised by a patient's own teeth. He also referred to Dr. Black's amalgam experiments.

After the reading of this the Chairman introduced the new President, Mr. W. BOWMAN MACLEOD, of Edinburgh, who was very heartily received. He referred in appreciative terms to the late Sir John Tomes, whose loss the Association had recently to lament. He also acknowledged and thanked the University authorities for the readiness with which they had placed at their disposal whatever accommodation was required for the meeting. He then touched upon historical points connected with the University and interesting to their profession. The University had been established in the reign of James VI. of Scotland who became James I. of England, and he quoted evidence to show that that pedantic monarch was sufficiently interested in dentistry to have himself drawn several teeth. He traced the relation between the University and the city authorities, who had cared for and fostered the town's college and protected it through many perilous years. Referring to the influence Goodsir had in developing the University as a teacher of anatomy, he mentioned that Goodsir had served his time to Nasmyth, the father of Scottish dentistry, and that probably much of his success was due to the training he had received as an apprentice. He dwelt upon the advances made in surgery during the past half century, and on those also which had been made in their own profession. One of the principal factors towards the betterment of their profession had been the establishment of dental hospitals, in which the youth of their profession were being educated in the possibilities of conservative dentistry, and in which the public were being taught that by a little timely attention many an errant tooth could be restored to health and usefulness. Their hospitals were good, but he complained of the meagre assistance they got from the wealthy and well-to-do. Good as their hospitals were, they would never be what they might and ought to be until they could support a chair

Digitized by Google

in clinical dental surgery. Other divisions of study had claims for considerations, and chairs for these would come in time, but this one had, to his mind, the most urgent claims and should be the primary object of their efforts in shaping the immediate future of their educational institutions. The occupant of such a chair would require to be a man of experience, who would devote much of his time to teaching and superintending the work, and one whose knowledge and experience would give authority to his instruction and directions. The great want was the lack of money. He considered the possible channels by which they might get money. Money out of Imperial funds could not be relied upon, although he was not without hope that help might be given to them some day from that quarter. They had mainly to look to themselves and to the ever-increasing class of wealthy persons who were looking for channels into which they could direct surplus wealth where it would be utilised for the amelioration of distress. That they had so little encouragement in the past from this source was because they were young. Other and older institutions had claimed attention. Here was something to interest themselves in, a fresh development to stimulate them to renewed and increased energy, a fresh and additional plea to place before those who had helped in the past, and a stronger and broader claim to urge on those from whom they would seek assistance in the future.

On the motion of Mr. NEALE (Birmingham), seconded in humorous terms by Dr. CAMPBELL (Dundee), a vote of thanks was very heartily accorded Mr. Macleod for his address. At this stage Principal Sir WILLIAM MUIR entered, and in a few suitable words welcomed the Association to the University and commented on the importance of the dental profession.

The TREASURER'S report showed a satisfactory state of the funds and a considerable sum on hand and on deposit receipt.

The SECRETARY'S report dealt with a variety of legal cases. The object of prosecutions was not so much the expectation of arresting the evil of illegitimate practice, but rather to establish the meaning of the Act of Parliament and thereby to gather experience and power to grapple with the evil in a more extensive and efficient way at a not distant future. The question of "covering" was referred to as a fruitful source of imposition and injury to the general public. The question of direct representation on the General Medical Council had also received attention, but the progress had not realised the expectations of the more sanguine. Their claim was still before the Privy Council. The committee for the collective investigation of the teeth of school children was still at work, and though working in silence it would tend more to forward the Association's reputation in public estimation than perhaps any other influence at their disposal.

It was intimated that the next meeting was to be held in London in 1896, and that Mr. FREDERICK CANTON, L.R.C.P. Lond., was the President-elect.

In the microscopical section Mr. MUMMERY (London) delivered an address on the Progress of Microscopy in Dentistry.

In the report on school children's teeth it was stated that 700 children had been reported on during the year, bringing the total number examined up to 11,422. The investigations showed that teeth inevitably decayed as age advanced, and that the teeth of the children of the wealthy classes seemed more prone to decay than those of poor charity children.

Dr. FREDERICK HEWITT (London) read a paper in the afternoon entitled, "An Inquiry into the Safety and Sphere of Applicability of Chloroform as an Anæsthetic in Dental Surgery." He had endeavoured to obtain particulars of every fatality which had occurred in the British Isles during the past fifteen years. Although deaths from all general anæsthetics were included, a special analysis was made of chloroform fatalities. These constituted a very large proportion of the total number, and were so numerous that it was contended the time had come for the expression of some authoritative statement as to the proper sphere of applicability of chloroform in dental surgery. While admitting the value of chloroform in general surgery, dental operations differed widely from major surgical operations in that the general circumstances under which they took place were not nearly so favourable so far as the anæsthetic was concerned. It was, therefore, clear that there was special need in dental surgery for the employment of anæsthetics with a wide margin of safety—a quality with which chloroform was certainly not endowed. He contended that, with such an alarming death-rate from chloroform in this branch of practice, this anæsthetic should only be used under very exceptional circumstances, and that ether—an equally satisfactory agent when properly administered—should be chosen when the operation was such that nitrous oxide was inadmissible. He maintained that it was the duty of everyone who was called upon to administer an anæsthetic for a dental operation to employ that one which was least likely to destroy life. For short operations nitrous oxide should be selected, for longer ones ether, and chloroform should only be chosen for exceptional cases. The number of deaths during the period referred to was 37. Of these, 14 occurred in Scotland, 21 in England and Wales, and 2 in London. The discussion of this paper was postponed until the following day, but it may be referred to here.

Dr. D. WALLACE opened the discussion. He said that with regard to the deaths it was to be remembered that they did not know how often the various anæsthetics had been used, and he was inclined to think that probably chloroform was most used. In the Dental Hospital in Edinburgh he understood that within recent years probably over 300 cases had been chloroformed and no accident had occurred. Taken all over it seemed to be granted that ether was safer than chloroform, also he held that maladministration was much less probable with ether than with chloroform, as the former was given by special anæsthetists as a rule, while chloroform was given by all and sundry. He condemned operating during light anæsthesia. He also considered chloroform more convenient than ether. As to the causes of accidents from chloroform, he thought that even such discussions as they were engaged in tended to engender a feeling of terror about chloroform and they were led into the risk of giving too little. He followed Syme and Simpson in giving it and in attending to the respiration only. He disapproved of feeling the pulse, as the pulse became feeble if the patient became sick, and sickness was an indication to push the anæsthetic. His two points were that the patient should be recumbent, and that nothing should interfere with free respiration.—Mr. COLYER argued in favour of nitrous oxide gas and said that other anæsthetics were very seldom necessary.—Dr. WILLIAMSON (Aberdeen) pointed out that the medical men recommended chloroform in Scotland.—Dr. HEWITT, in reply, insisted that if it were shown that ether was safer than chloroform it was their duty to use it, and the medical men ought to be educated in the administration of it.

Mr. ROBBINS (London) read a practical paper on the Use of Amalgams in Everyday Practice, in which he strongly advocated their utility.

Mr. HERN (London) read a paper on Oral Hygiene, in which he referred to the care of the teeth.

Mr. G. CUNNINGHAM (Cambridge) made a communication entitled "What the Dentist can do for the State," in which he pointed out the importance of attending to the teeth, and how this point was entirely neglected, and suggested that there should be State dental officers.

Various interesting and instructive demonstrations were given, the most interesting of which was, perhaps, that by Mr. FRASER (Inverness) in which he used the electric mallet, and showed the method of adjusting a Logan crown to a front tooth. Methods of taking casts and the uses of electricity in dentistry were demonstrated.

The scientific part of the meeting was satisfactory and successful, and the weather was fairly propitious for social functions and sight-seeing. On the evening of the opening day the Lord Provost and magistrates gave a reception. On Aug. 30th the annual dinner was held, and Mrs. Bowman Macleod gave a successful and pleasant reception in the evening. On Aug. 31st there was an excursion to Loch Lomond, and the last general meeting was held in the Tarbet Hotel.

THE CASE OF MR. R. B. ANDERSON.

THE Civil Rights' Defence Committee, 3, Mitre-court, Temple, E.C., is making active endeavours to obtain some redress for Mr. Anderson, and in furtherance of this object a deputation, headed by the Right Hon. the Earl of Stamford, had an interview with several members of Parliament on Aug. 29th in the Conference Room of the House of Commons. Earl Stamford, after a review of the whole case,

Digitized by Google

an account of which recently appeared in our columns,[1] explained that the illegal judgments and orders of the colonial courts are still in force against Mr. Anderson, and that he is anxious to appeal to the Privy Council to have them cancelled, but has hitherto been prevented by lack of funds. General Graham, following Earl Stamford, stated that the colonial judges, among other illegal acts, incited and permitted speculative and fraudulent suits to be brought *in formâ pauperis* against Mr. Anderson, the plaintiffs not being paupers, and the affidavits of poverty and of the facts required by law being systematically dispensed with, contrary to the provisions of the Bill of Rights. In these suits Mr. Anderson was illegally denied his right to give evidence, he was deprived of his lawful professional charges, and penal damages were inflicted on him for lawfully exercising his right of retiring from a medical case and for lawfully recovering possession of his freehold land. To enforce these judgments he was illegally committed to prison and refused the writ of habeas corpus, excessive bail was illegally exacted (£1000 in civil claims of £42), and judgment in his appeals against these orders was withheld for three and a half months in order to keep him under restraint. Finally, having come to England and gained an action against the colonial judges, he was deprived of damages on the ground that no action could lie against a judge for acts done in his judicial capacity. The deputation urged that if this be the state of the law then it is essential in the interest of individual rights and liberties that some remedy for such abuses and some redress for such wrongs should be devised.

Messrs. Benjamin L. Cohen, M.P., H. Dalziel, M.P., W. Jones, M.P., J. Herbert Lewis, M.P., and Reginald McKenna, M.P., having assured the deputation of their sympathy and their intention to give the matter the utmost consideration, it was arranged that a second conference should be held at an early date. Dr. Ward Cousins (Southsea) then spoke at some length on the bearings of the case in relation to the medical profession, and the proceedings terminated.

A VISIT TO PROFESSOR KITASATO'S INSTITUTE FOR INFECTIOUS DISEASES.

BY J. M. ATKINSON, M.B. LOND., M.R.C.S. ENG., L.S.A.,
COLONIAL SURGEON, HONG-KONG.

ON July 28th I visited this institution and was shown round by Professor Kitasato, Dr. Nakagawa, a Japanese gentleman who is a graduate in medicine of New York University, acting as interpreter. Professor Kitasato, although having an intimate knowledge of German, does not speak English. We first proceeded to the laboratory, and I was shown the following specimens: (1) tubercle bacilli; (2) plasmodium malariæ; (3) pneumococcus (Fränkel's); (4) Löffler's bacillus; (5) tetanus bacillus; (6) bacillus anthracis; (7) plague bacillus; (8) lepra bacillus; (9) typhus fever (enteric fever) bacillus; (10) cholera bacillus; and (11) gonococcus. Professor Kitasato's method of obtaining the plasmodium malariæ is first to fix the specimen with a 1 per cent. solution of corrosive sublimate, afterwards staining with a saturated solution of eosin in absolute alcohol and then with Löffler's solution of methylene blue. With reference to diphtheria I had a long conversation with Professor Kitasato. He has succeeded in obtaining an antitoxin much stronger than any yet used. To show this 9 c.c. of his serum are all that he injects to cure a case of diphtheria; with Roux's serum, on the other hand, it is necessary to use as much as 100 c.c. He can obtain this from the blood of a horse, but prefers that of a sheep. I was shown large pieces of diphtheritic membrane which had been coughed up by patients who had been injected with this antitoxin. The "tetanus bacillus" was a beautiful specimen and is shaped somewhat like a clove, the head being the spore, and is stained red with carbolised fuchsine, the body of the bacillus being stained blue. The sixth specimen showed the spore formation very well, the spores being, as in the previous case, stained with fuchsine and the bacilli with methylene blue. The plague bacilli are very distinctive and are exactly similar to those which were obtained this year from the few plague cases which have occurred in Hong-kong. They are of an oval shape, presenting two deeply stained poles with a clear non-stained interval between them. The simplest way to obtain the plague bacilli is to take some of the juice from one of the affected lymphatic glands, smear it on a cover-glass, and, after fixing, stain with eosin or methyl blue. Bacilli are found to be present in great numbers; they are almost identical in appearance with those of chicken cholera. The bacillus of enteric fever, which was quite new to me, presents a deeply stained body with a number of fine filamentous processes passing off from it; none of these are branched. The specimen was from a culture obtained from the fæces in a typhoid fever case. After this I was taken round the menagerie, where there was a large number of animals—guinea-pigs, dogs, rabbits, mice, monkeys, &c.—for the purposes of inoculation, investigation, &c., and finally I visited the wards. In one room there were two patients convalescent from diphtheria who had been injected with Professor Kitasato's antitoxin; in another ward he showed me a case of leprosy in which the tubercles were disappearing under the influence of an antitoxin which he is now investigating. In another ward there was a child with traumatic tetanus; this case was also on a fair road to recovery, the seizures being much less since the injection of a tetanus antitoxin and the temperature having fallen after each injection. There were also some twelve cases of phthisis. Just off the wards there was a Lyons steam disinfector. The laboratory was furnished with every requisite, and one could not but be convinced that here, in the middle of Tokio, some excellent scientific research is being carried on by Professor Kitasato and his assistants.

[1] THE LANCET, Aug. 31st, 1895

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Bristol Urban Sanitary Authority.—The population of Bristol proper was estimated to the middle of 1894 as 226,578; it is, however, well to note that the city itself is practically continuous on two of its sides with other urban districts containing an aggregate population of 59,509, so that in reality the population of which Bristol forms the centre amounts to nearly 300,000. It is obviously important to have regard to this consideration in estimating the value of Bristol's death-rates &c. The population of Bristol had up to the time of the result of the 1891 Census been known to be considerably over-rated, the over-estimation having been in 1891 no less than 10,199. The corrected general death-rate of Bristol for 1894 was 17·92 per 1000, the lowest yet recorded for the city; the infantile mortality for the same period was 148·3 per 1000 births. In commenting upon diphtheria Dr. D. S. Davies observes that the tendency of this disease to increase in the large urban districts of England and Wales is now unhappily shown in Bristol, although the death-rate for this district is found still to compare favourably with that of the thirty-three great towns. With regard to phthisis Dr. Davies considers that hospital isolation as is practised in other infectious diseases is not possible in this, but he thinks that good results would accrue from its notification. Bristol seems to be in a fair way to provide itself with satisfactory isolation accommodation, the urban sanitary authority having procured sites for the separate isolation of small-pox and other infectious diseases. The relations of Bristol to the surrounding urban sanitary districts already referred to would seem to indicate some joint hospital scheme as the most economical.

Huddersfield Urban Sanitary Authority.—Dr. J. R. Kaye reports that for the third year in succession the general death-rate of Huddersfield has been the lowest on record since the incorporation of the borough, the rate for 1894 being 15·9 per 1000 of the population. These gratifying results are, Dr. Kaye remarks, "largely the reward of wise sanitary work, but corporate action is not limitless and much may be ascribed to favourable atmospheric conditions." The birth-rate of the district was for 1894 but 20·25 per 1000, there having been a very marked decline in this respect since 1878, when the birth-rate was 35 per 1000. Among the thirty-three large towns the nearest approach during 1894 to the birth-rate of Huddersfield was that of Halifax, 23·1

Digitized by Google

per 1000 births. In connexion with the low birth-rate of Huddersfield Dr. Kaye points out in his report that its ultimate effect will be to produce an age distribution of the population favourable to an increased death-rate. The infantile mortality of Huddersfield for 1894 was 160 per 1000 births, as against one of 152 for the thirty-three large towns. The subject of providing a proper fever hospital for Huddersfield has, Dr. Kaye tells us, been "driven from pillar to post" for the last decade, but there is, it seems, a fair prospect of a suitable building being shortly erected. In connexion with the subject of food-supply Dr. Kaye points out—and it is certainly a very important consideration—that, although since the erection of the abattoir a large amount of the meat sold in the borough is supervised, the sale of carcases brought from other towns is on the increase; and he observes that these difficulties point to a national system of inspection of all animals intended for human consumption. Unfortunately, in the case of England—dependent as it is, in large part at least, upon foreign meat—the inspection of home-raised cattle would form but a small part of the supervision necessary, and the introduction of foreign carcases from abroad presents a further difficulty. If the result of a rigid inspection of home produce is to increase foreign importation, the advantages from the standpoint of public health are not altogether obvious. As regards the smoke nuisance in Huddersfield, Dr. Kaye reports that the recent bad trade and a poor quality of coals have tended to increase it. A complete survey of the principal streams in Huddersfield has recently been made, and the pollutions discovered are to be immediately rectified on the completion of a new sewer. The conditions of the rivers Holme and Colne are now receiving the attention of the Rivers Board, and Dr. Kaye expresses a hope that some improvement will soon result. At the present time, he states, the condition of these two rivers as they enter Huddersfield is filthier than when they leave it. If this is so the corporation of Huddersfield will have much to gain and nothing to lose by supporting the action of the Rivers Board.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6321 births and 4042 deaths were registered during the week ending Aug. 31st. The annual rate of mortality in these towns, which had been 19·1 and 19·9 per 1000 in the two preceding weeks, was again 19·9 during the week ending Aug. 31st. In London the rate was 15·9 per 1000, while it averaged 22·8 in the thirty-two large provincial towns. The lowest rates in these towns were 14·2 in Bristol, 15·0 in Halifax, 15·9 in London and in West Ham, and 16·1 in Leicester; the highest rates were 31·0 in Sunderland, 31·3 in Hull, 34·1 in Bolton, and 35·6 in Burnley. The 4042 deaths included 1071 which were referred to the principal zymotic diseases, against 929 and 977 in the two preceding weeks; of these, 762 resulted from diarrhœa, 99 from measles, 65 from whooping-cough, 56 from diphtheria, 43 from scarlet fever, 40 from "fever" (principally enteric), and 6 from small-pox. In the large towns these diseases caused the lowest death-rates in Swansea, Plymouth, Bristol, Croydon, London, and Huddersfield; and the highest rates in Blackburn, Hull, Sunderland, Bolton, and Burnley. The greatest mortality from measles occurred in West Ham and in Blackburn; from whooping-cough in Bradford; and from diarrhœa in Blackburn, Norwich, Sunderland, Hull, Bolton, and Burnley. The mortality from scarlet fever and from "fever" showed no marked excess in any of the large towns. The 56 deaths from diphtheria included 40 in London, 4 in Birmingham, and 3 in Liverpool. Four deaths from small-pox were registered in London, 1 in Oldham, and 1 in Preston, but not one in any other of the thirty-three towns. There were 341 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday, Aug. 31st, against 273, 336, and 357 at the end of the three preceding weeks; 36 new cases were admitted during the week, against 54, 79, and 65 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of August was 2512, against 2511, 2529, and 2507 on the three preceding Saturdays; 264 new cases were admitted during the week, against 276, 357, and 307 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 137 and 170 in the two preceding weeks, declined again to 102 during the week ending the 31st ult., and were 51 below the corrected average. The causes of 44, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Portsmouth, Newcastle, Bradford, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Salford, Blackburn, and Sheffield.

In thirty-three of the largest towns 6329 births and 4050 deaths were registered during the week ending Sept. 7th. The annual rate of mortality in these towns, which had been 19·9 per 1000 in each of the two preceding weeks, was again 19·9 last week. In London the rate was 16·1 per 1000, while it averaged 22·6 in the thirty-two provincial towns. The lowest rates in these towns were 11·1 in Plymouth, 12·4 in Swansea, 12·5 in West Ham, 13·2 in Croydon, and 15·3 in Bristol; the highest rates were 33·8 in Preston, 34·7 in Blackburn, 35·6 in Hull, 37·1 in Wolverhampton, and 40·5 in Sunderland. The 4050 deaths included 1071 which were referred to the principal zymotic diseases, against 977 and 1071 in the two preceding weeks; of these, 775 resulted from diarrhœa, 75 from measles, 66 from whooping-cough, 62 from diphtheria, 49 from "fever" (principally enteric), 37 from scarlet fever, and 7 from small-pox. These diseases caused the lowest death-rates in Plymouth, Bristol, Swansea, and Croydon, and the highest rates in Burnley, Wolverhampton, Blackburn, Sunderland, and Hull. The greatest mortality from measles occurred in West Ham, Salford, and Blackburn; from whooping-cough in Wolverhampton, Bolton, Bradford, and Gateshead; from "fever" in Sunderland; and from diarrhœa in Wolverhampton, Blackburn, Burnley, Sunderland, Preston, and Hull. The mortality from scarlet fever showed no marked excess in any of the large towns. The 62 deaths from diphtheria included 38 in London, 4 in Birmingham, 4 in Leeds, and 3 each in Wolverhampton, Birmingham, and Liverpool. Five fatal cases of small-pox were registered in London, one in Manchester, and one in Oldham, but not one in any other of the thirty-three towns. There were 328 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 7th inst., against 336, 342, and 340 at the end of the three preceding weeks; 25 new cases were admitted during the week, against 79, 65, and 36 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2600, against 2529, 2507, and 2512 on the three preceding Saturdays; 336 new cases were admitted during the week, against 357, 306, and 264 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 170 and 102 in the two preceding week, rose again to 134 last week, but were 21 below the corrected average. The causes of 47, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Cardiff, Leicester, Nottingham, Bradford, and in eleven other smaller towns; the largest proportions of uncertified deaths were registered in West Ham, Bristol, Wolverhampton, and Birmingham.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·6 in each of the two preceding weeks, rose to 17·3 during the week ending Aug. 31st, and was 2·6 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·8 in Paisley, 15·6 in Edinburgh, and 15·7 in Leith to 18·2 in Dundee and 24·0 in Perth. The 499 deaths in these towns included 78 which were referred to diarrhœa, 12 to whooping-cough, 10 to "fever," 8 to scarlet fever, 5 to measles, 5 to diphtheria, and not one to small-pox. In all, 118 deaths resulted from these principal zymotic diseases, against 99 and 83 in the two preceding weeks. These 118 deaths were equal to an annual rate of 4·1 per 1000, which was 1·2 below the mean rate during the same period from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined from 68 to 42 in the three preceding weeks, increased again to 78, of which 34 occurred in Glasgow, 15 in Dundee, and 12 in Edinburgh. The

Digitized by Google

deaths referred to whooping-cough, which had been 17, 15, and 24 in the three preceding weeks, fell again to 12, and included 7 in Glasgow and 3 in Aberdeen. The fatal cases of "fever," which had been 6 in each of the two preceding weeks, rose to 10, and of these 8 occurred in Glasgow. The deaths from scarlet fever, which had increased from 3 to 8 in the four preceding weeks, were again 8, of which 3 occurred in Glasgow, 3 in Leith, and 2 in Edinburgh. The fatal cases of measles, which had declined from 8 to 2 in the three preceding weeks, rose again to 5, and included 3 in Glasgow. The deaths from diphtheria, which had been 4 and 1 in the two preceding weeks, rose again to 5, of which 2 occurred in Glasgow. The deaths referred to diseases of the respiratory organs in these towns, which had been 57 and 55 in the two preceding weeks, were 54 during the week under notice, and were within one of the number in the corresponding week of last year. The causes of 16, or more than 3 per cent., of the deaths in these eight towns were not certified.

The annual rate of mortality in the eight Scotch towns, which had been 16·6 and 17·3 per 1000 in the two preceding weeks, further rose to 17·5 during the week ending Sept. 7th, but was 2·4 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 15·6 in Dundee and 16·7 in Dundee to 20·6 in Leith and in Perth, and 23·5 in Greenock. The 504 deaths in these towns included 74 which were referred to diarrhœa, 15 to whooping-cough, 8 to scarlet fever, 4 to "fever," 2 to measles, 2 to diphtheria, and not one to small-pox. In all, 105 deaths resulted from these principal zymotic diseases, against 83 and 118 in the two preceding weeks. These 105 deaths were equal to an annual rate of 3·6 per 1000, which was 1·8 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 42 and 78 in the two preceding weeks, were 74 last week, of which 26 occurred in Glasgow, 22 in Edinburgh, and 14 in Dundee. The deaths referred to whooping-cough, which had been 15, 24, and 12 in the three preceding weeks, rose again to 15 last week, and included 7 in Glasgow and 3 in Dundee. The 8 fatal cases of scarlet fever corresponded with the number in the preceding week, and included 4 in Glasgow and 2 in Leith. The deaths referred to different forms of "fever," which had been 6 and 10 in the two preceding weeks, declined to 4 last week, of which 2 occurred in Glasgow. The 2 fatal cases of diphtheria were recorded in Edinburgh and the 2 deaths from measles in Greenock. The deaths referred to diseases of the respiratory organs in these towns, which had been 55 and 54 in the two preceding weeks, were 56 last week, and slightly exceeded the number in the corresponding week of last year. The causes of 33, or nearly 7 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 24·0 and 29·0 in the two preceding weeks, rose again to 23·6 during the week ending Aug. 31st. During the first nine weeks of the current quarter the death-rate in the city averaged 23·4 per 1000, the rate during the same period being 19·6 in London and 16·4 in Edinburgh. The 158 deaths registered in Dublin during the week under notice showed an increase of 18 upon the number in the preceding week, and included 20 which were referred to the principal zymotic diseases, against 21 and 11 in the two preceding weeks; of these, 12 resulted from diarrhœa, 5 from "fever," 3 from whooping-cough, and not one from small-pox, measles, scarlet fever, or diphtheria. These 20 deaths were equal to an annual rate of 3·0 per 1000, the zymotic death-rate during the same period being 3·3 in London and 3·0 in Edinburgh. The fatal cases of diarrhœa, which had decreased from 23 to 9 in the three preceding weeks, rose again to 12 during the week under notice. The mortality from "fever" and from whooping-cough showed an increase. The 158 deaths in Dublin included 35 of infants under one year of age, and 39 of persons aged upwards of sixty years, the deaths both of infants and of elderly persons showing an increase. Six inquests were held and 5 deaths from violence were registered; and 43, or more than one-fourth, of the deaths occurred in public institutions. The causes of 20, or nearly 13 per cent., of the deaths in the city last week were not certified.

The death-rate in Dublin, which had been 20·9 and 23·6 per 1000 in the two preceding weeks, declined again to 22·2 during the week ending Sept. 7th. During the past ten weeks of the current quarter the death-rate in the city has averaged 23·3 per 1000, the rate during the same period being 19·2 in London and 16·5 in Edinburgh. The 149 deaths registered in Dublin during the week under notice showed a decline of 9 from the number in the preceding week, and and included 13 which were referred to the principal zymotic diseases, against 11 and 20 in the two preceding weeks; of these, 8 resulted from diarrhœa, 2 from whooping-cough, 1 from scarlet fever, 1 from diphtheria, 1 from "fever," and not one either from small-pox or measles. These 13 deaths were equal to an annual rate of 1·9 per 1000, the zymotic death-rate during the same period being 3·2 in London and 5·1 in Edinburgh. The fatal cases of diarrhœa, which had been 9 and 12 in the two preceding weeks, declined again to 8 last week. The mortality from whooping-cough and from "fever" showed a decline from that recorded in the preceding week. The 149 deaths in Dublin last week included 31 of infants under one year of age and 28 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a decline from the numbers in the preceding week. Six inquest cases and 6 deaths from violence were registered; and 40, or more than a fourth, of the deaths occurred in public institutions. The causes of 10, or nearly 7 per cent., of the deaths in the city last week were not certified.

VITAL STATISTICS OF LONDON DURING AUGUST, 1895.

In the accompanying table will be found summarised complete statistics relating to sickness and mortality during August in each of the forty-three sanitary areas of London. With regard to the notified cases of infectious disease in the metropolis during last month, it appears that the number of persons reported to be suffering from one or other of the nine diseases specified in the table was equal to 9·9 per 1000 of the population, estimated at 4,392,346 persons in the middle of the current year. In the three preceding months the rates had been 6·8, 8·4, and 11·6 per 1000 respectively. Among the various sanitary areas the rates were considerably below the average in St. George Hanover-square, Westminster, Hampstead, St. Martin-in-the-Fields, St. Olave Southwark, Lewisham, and Lee; while they showed the largest excess in Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, and St. Saviour Southwark. The prevalence of small-pox in London showed a further increase in August, 231 cases being notified during the month, including 37 in Bethnal Green, 28 in Whitechapel, 22 in Camberwell, 21 in Mile End Old Town, 11 in St. George-in-the-East, and 11 in St. George Southwark sanitary areas. The Metropolitan Asylum Hospitals contained 331 small-pox patients at the end of August, against 20, 33, and 232 at the end of the three preceding months; the weekly admissions averaged 57, against 5, 10, and 49 in the three preceding months. The prevalence of scarlet fever in London showed a slight decline during August; this disease was proportionally most prevalent in Strand, Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, and St. Saviour Southwark sanitary areas. The Metropolitan Asylum Hospitals contained 2435 scarlet fever patients at the end of August, against 1481, 1845, and 2340 at the end of the three preceding months; the weekly admissions averaged 292, against 167, 229, and 263 in the three preceding months. The prevalence of diphtheria in London showed a marked decline during the month under notice; among the various sanitary areas this disease showed the highest proportional prevalence in Bethnal Green, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, Camberwell, and Greenwich. There were 666 cases of diphtheria under treatment in the Metropolitan Asylum Hospitals at the end of August, against 508, 633, and 680 at the end of the three preceding months; the weekly admissions averaged 80, against 81, 109, and 103 in the three preceding months. The prevalence of enteric fever in London showed a marked increase during August; this disease was proportionally most prevalent in Kensington, Fulham, City of London, St. George-in-the-East, Limehouse, Mile End Old Town, Camberwell, and Woolwich sanitary areas. Erysipelas was proportionally most prevalent in Kensington, Holborn, Shoreditch, Bethnal Green, Whitechapel, and St. George-in-the-East sanitary areas. The 23 cases of puerperal fever notified during August included 3 in Hackney and 3 in Greenwich sanitary areas.

The mortality statistics in the accompanying table relate

to the deaths of persons actually belonging to the various sanitary areas, the deaths occurring in the institutions of London having been distributed among the different sanitary areas in which the patients had previously resided. During the four weeks ending Saturday, Aug. 31st, the deaths of 5687 persons belonging to London were registered, equal to an annual rate of 16·9 per 1000 of the population, against 15·9, 14·9, and 21·0 in the three preceding months. The lowest death-rates during August in the various sanitary areas were 10·1 in Hampstead, 10·4 in Stoke Newington, 11·1 in St. George Hanover-square, 11·8 in St. James Westminster, 12·2 in Lewisham (excluding Penge), 12·3 in Wandsworth, and 12·5 in St. Martin-in-the-Fields; the highest rates were 25·5 in Holborn, 25·6 in Whitechapel, 28·0 in St. Olave Southwark, 28·5 in St. Saviour Southwark, 28·7 in Limehouse, 29·4 in St. Luke, and 31·1 in St. George-in-the-East. During the four weeks of August 1237 deaths were referred to the principal zymotic diseases in London; of these, 613 resulted from diarrhœa, 243 from measles, 167 from diphtheria, 84 from scarlet fever, 73 from whooping-cough, 42 from enteric fever, 14 from small-pox, and 1 from typhus. These 1237 deaths were equal to an annual rate of 3·7 per 1000; the lowest zymotic death-rates were recorded in St. George Hanover-square, St. James Westminster, Hampstead, Stoke Newington, St. Martin-in-the-Field, Strand, and Lee; and the highest rates in St. Luke, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, Poplar, and St. Olave Southwark sanitary areas. Fourteen fatal cases of small-pox were registered in London during the month under notice, the corrected average in the corresponding periods of the ten preceding years being 6; of these 14 fatal cases 3 belonged to Whitechapel and 2 to Bethnal-green sanitary areas. The 243 deaths referred to measles were 91 above the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Holborn, St. Luke, Whitechapel, St. George-in-the-East, Limehouse, Mile End Old Town, and Bermondsey. The 84 fatal cases of scarlet fever almost corresponded with the corrected average number; this disease showed the highest proportional fatality in Strand, St. George-in-the-East, Limehouse, and Mile End Old Town sanitary areas. The 167 deaths referred to diphtheria were 45 above the corrected average number; among the various sanitary areas this disease was proportionally most fatal in Shoreditch, Bethnal Green, Whitechapel, St. George-in-the-East, Mile End Old Town, Poplar, and Greenwich. The 73 fatal cases of whooping-cough were little more than half the corrected average number; this disease showed the highest proportional fatality in Limehouse, Poplar, and Greenwich sanitary areas. The 42 deaths referred to enteric fever were within 6 of the corrected average number; there was no marked excess of "fever" mortality last month in any of the sanitary areas. The 613 fatal cases of diarrhœa were 102 below the corrected average number; among the various sanitary areas this disease showed the highest proportional fatality in Fulham, St. Luke, St. George-in-the-East, St. Saviour Southwark, Rotherhithe, and Plumstead. In conclusion, it may be stated that the mortality in London during August from these principal zymotic diseases was very slightly below the average.

Infant mortality in London during August, measured by the proportion of deaths under one year of age to registered births, was equal to 189 per 1000, and was below the average. Among the various sanitary areas the lowest rates of infant mortality were recorded in St. George Hanover-square, St. James Westminster, Islington, Stoke Newington, St. Giles, and Bermondsey; and the highest rates in Strand, Holborn, City of London, Limehouse, St. Saviour Southwark, and St. Olave Southwark.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

THE following officers have received orders to proceed to India at an early date:—Surgeon-Lieutenant-Colonel Brown, Surgeon-Majors Lane, Coates, Haywood, Peterkin, Rhodes, and O'Keefe, and Surgeon-Captain Durant. Surgeon-Captain Adamson has arrived from Egypt on leave. Brigade-Surgeon-Lieutenant-Colonel Macnamara has assumed Charge of the Station Hospital at Fermoy. Surgeon-Captain M. L. Hearn is ordered to hold himself in readiness to proceed to the Straits Settlements for duty. The following officers have embarked in the *Victoria* for a tour of service in India:—Surgeon-Lieutenant-Colonel Blood, Surgeon-Major Burton, and Surgeon-Lieutenants Pollock, Rivers, Longhurst, Symons, and Buswell. Surgeon-Major Kirkpatrick has been appointed to Winchester. Surgeon-Captain Birch has been invalided from Bombay, and Surgeon-Captain Day has returned to Malta from leave of absence. Surgeon-Major Russell has arrived in England from Gibraltar. Surgeon-Colonel Muir will shortly proceed to India in relief of Surgeon-Colonel Wilson, tour expired.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following admissions to the Indian Medical Service:—To be Surgeon-Lieutenants: *Bengal:* John Stephenson, Frank Needham Windsor, Walter Barrie Turnbull, Ernest Edwin Waters, Asher Leventon, and Philip Francis Chapman. *Madras:* Frederick Linton Blenkinsop, Alfred Moore, Edmund Moritz Illington, Thomas Edgar Watson, and Charles George Webster. *Bombay:* Alfred Hooton, Arthur Frederick William King, Robert Frazer Standage, Andrew Armstrong Gibbs, and Henry Alfred Forbes Knapton. The following appointments are announced:—Surgeon-Captain J. B. Jameson, Officiating Medical Officer, 5th Bombay Cavalry and Officiating Civil Surgeon, Jacobabad, is appointed to officiate as Medical Officer of the 2nd Regiment Central India Horse, and of the Goona Political Agency until further orders. Surgeon-Lieutenant-Colonel J. McConaghy, Civil Surgeon, Lucknow, to hold Charge of the current duties of the office of Inspector-General of Civil Hospitals, North-West Provinces and Oudh, in addition to his other duties, until further orders. Surgeon-Lieutenant-Colonel G. C. Hall, Officiating Inspector-General of Prisons, North-West Provinces and Oudh, on being relieved by Sir John Tyler, to revert to his substantive appointment as Superintendent, Central Prison, Allahabad. Surgeon-Captain H. W. Elphick, Officiating Superintendent, Central Prison, Allahabad, on being relieved by Surgeon-Lieutenant-Colonel G. C. Hall, to be Civil Surgeon, Muzaffarnagar. Brigade-Surgeon-Lieutenant-Colonel B. Franklin, Surgeon to the Viceroy, is appointed to hold Charge of the office of Inspector-General of Civil Hospitals in the Punjab, in addition to his own duties, until further orders. Surgeon-Captain H. J. Dyson, Deputy Sanitary Commissioner in the Punjab, is appointed to be Sanitary Commissioner of Bengal. Surgeon-Colonel A. F. Churchill, A.M.S., is brought on the Administrative Medical Staff of the Army. A good service pension has been conferred on Surgeon-Colonel L. D. Spencer, M.D., in place of Surgeon-Major-General W. R. Rice, M.D., retired. Brigade-Surgeon-Lieutenant-Colonel, A. Barry, M.D., Bombay Establishment, 6th Regiment of Bombay Cavalry (Jacob's Horse), retires from the service.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff-Surgeons: E. R. Dimsey to the *Sappho;* S. W. Johnson to the *Melita;* E. J. Biden to the *Scout;* Donald T. Hoskyns and Ernest E. Bray to the *Boscawen;* Alex. L. Christie to the *Camperdown;* J. A. McAdam to the *Grafton.* Surgeons: James Mowat to the *Albacore,* and W. R. Knightley to the *Camperdown.*

YEOMANRY CAVALRY.

Royal Wiltshire (Prince of Wales's Own Royal Regiment): Surgeon-Lieutenant G. T. K. Maurice resigns his commission.

VOLUNTEER CORPS.

Artillery: 1st Cheshire and Carnarvonshire: Surgeon-Major W. Bell resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Corps on his retirement. 1st Cumberland: James Brown Bird, M.B., to be Surgeon-Lieutenant. *Rifle:* 1st Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Lieutenant T. Johnston resigns his commission; also is permitted to retain his rank, and to continue to wear the uniform of the Battalion on his retirement. 9th Lanarkshire: Surgeon-Lieutenant C. Symington, M.B., resigns his commission.

THE WAR OFFICE REORGANISATION.

We confess that we are unable to understand the exact nature of the newly proposed scheme of War Office organisation or see how it is to accomplish the end in view or prove workable in practice. So far from clearly defining and fixing responsibility and simplifying matters generally, it seems to us that responsibility and power will be in future dissipated in a multitude of councils, and no one will be able to say in which of these or with whom the responsibility really resides. There is to be, first of all, a Commander-

Digitized by Google

in-chief as military head of the army just as there was before and is at the present time, not that this matters much, and it is on the whole desirable, we should say, to retain the title. But there is to be a Board, presided over by the Commander-in-chief, with four military members, who will be directly responsible for their departments to the Secretary of State. Next there is to be a War Office Council, presided over by the Secretary of State, of which the Commander-in-chief and the Under-Secretary and Financial Secretary will be members; to which is added apparently a third council, with specialised but higher functions, to complete the three-storeyed edifice. As regards the Army Board it will either happen that Lord Wolseley as president and military head of the army will practically and in effect constitute the board or be subjected to the risk of opposition and contention on the part of its independent members, who are subordinate to him in military rank, with the option of a direct appeal from any of them to the Secretary of State. There are other points, too, provocative of misgiving or criticism; but it is probable that when Parliament meets again the Government will have thoroughly considered the subject of the scheme as a whole. They will then have had time to weld the machinery together into something like a more perfectly adjusted and self-balanced scheme. We do not see that any place is given, by the way, for any direct representation of the medical service at any board or council.

THE CASE OF SURGEON-MAJOR CLARENCE SMITH AND THE MADRAS GOVERNMENT.

Our readers' attention has been already called to this matter, and there is no need to recapitulate the facts so far as they have been published. It will be remembered, however, that the Secretary of State for India had consented to reconsider the matter, and the Madras Government has consequently offered Surgeon-Major Smith the option of having the case further investigated before a Commission composed of a military officer and an officer of judicial experience, both sides to be allowed counsel and the right to call witnesses, but the Commission was to be neither judicial nor public. Mr. Clegg's letter was to have been read and Surgeon-Major Smith examined on it, as well as upon his memorial and certain private letters. It is understood that Surgeon-Major Smith has declined to accede to these terms. In our opinion this is to be regretted. The course hitherto pursued may have been a wrong one and unfair to the officer concerned; still, the present offer shows that there is a disposition now to get at the truth and to do Surgeon-Major Smith justice, and there is no reason to suppose that the members of the Commission would not be impartial and ready to listen to anything that could be adduced in his favour and to report thereon accordingly. The proposal to Surgeon-Major Smith may not have been of the nature or in the form that he would have preferred, but it nevertheless gave the opportunity of having the matter fully represented and examined from his as well as the Government point of view. According to the *Pioneer Mail* of the 21st ult., just received, we learn that in consequence of a telegram from the Secretary of State Surgeon-Major Smith has consented, under protest, to appear before the Commission. We think him well advised in doing so under the circumstances, and hope the result may be favourable to him.

THE STRENGTH OF THE ARMY MEDICAL STAFF.

The *Army and Navy Gazette* states that "rumours are abroad which indicate the probability of further reductions in the administrative ranks of the Army Medical Staff. From some thirty-five officers that were found in the Surgeon-Colonel's List (old style, deputy surgeon-generals) only twenty-four are now provided for in the Army Estimates. The pruning knife is, we understand, likely to be applied shortly to the Surgeon-Major-General's List."

UNIFICATION OF THE INDIAN MEDICAL SERVICES.

The *Pioneer Mail* says: "The unification of the Indian Medical Services in the three Presidencies will shortly be carried into effect. It is part and parcel of the Army Reorganisation scheme, and only awaits the formal sanction of the India Office. The three Services will be amalgamated, and will be worked as at present through the Surgeon-General with the Government of India."

ARMY MEDICAL STAFF.

[illegible]-Captain Arthur L. H. Dixon retires from the

The appointment of Brigade-Surgeon-Lieutenant-Colonel Notter as Professor of Military Hygiene at the Army Medical School, Netley, has been renewed for a second term of office.

The War Office authorities, having decided to largely extend the military hospital at Stoke, Plymouth, are stated to be negotiating for the purchase of a site of about four acres for the purpose. It is intended to erect four new blocks, for 100 patients each, with additional quarters for medical officers.

Correspondence.

"Audi alteram partem."

"THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK."

To the Editors of THE LANCET.

SIRS,— I have been much interested in reading the remarks upon the physiology of death by electric shock which have recently appeared in THE LANCET.[1] The conclusion arrived at by Dr. A. M. Bleile of Ohio is "that death in electric shock is really due to the fact that the current produces a contraction of the arteries through an influence on the nervous system, and that this constriction of the arteries throws in such a mechanical impediment to the flow of the blood as the heart is unable to overcome." The grounds upon which this conclusion is based, being well established by a series of investigations and experiments, are, in my opinion, incontestable. But from these indisputable facts there arises a subject for consideration which is both of very deep interest and of very great importance. It is the question of the precise manner in which the electric force is productive of the observed results. This is a question which has a widely extended and most intimate and essential connexion with all biological phenomena.

I venture to hope that you will be able to afford space in THE LANCET for the solution which I offer of this interesting problem, the more especially as the investigations which I have conducted through a long series of years assure me that it is quite impossible to separate the physics of the cause of death under the conditions named from the physics which are continuously operating to maintain the phenomena of life, except as regards the quantity of the current which traverses the body in a given time. I will explain as briefly as possible the mode in which, as it appears to me, the observed phenomena are brought about. The points to be noticed are as follows: (1) the left side (of the heart) is completely relaxed and the right side intensely gorged with blood, as also are the large veins in the immediate vicinity of the heart; and (2) the arteries are contracted down to a very small calibre. The cause of these phenomena will be more readily seen if I reverse the order in which they are enumerated. 1. The contraction of the arteries is unquestionably due to a physical cause acting primarily upon the contents of the vessels—i.e., the blood—and secondarily through the blood upon the nerve and muscular fibres which enter into the composition of their structures. This physical cause is the passage of the electric current, and its effect is first produced in the arteries for the following reason: the arteries and veins are both filled with blood, but the magnetic charge in the arterial blood is greater than in the venous blood.[2] This difference in the amount of magnetic charge is due to the oxygen which has been absorbed during the circulation of the blood through the lungs, and is in proportion to the oxyhæmoglobin which has been formed thereby. The electric force is therefore drawn to the arteries and passes through them, producing simultaneously, in accordance with a well-established principle, a contraction of the nervous and muscular fibres with which the highly electrified blood is associated. 2. The electric current in its passage through the arteries in proportion to its electromotive force carries with it the blood which they contain, and on leaving the body deprives this arterial blood of its active magnetic properties. This removal of the magnetism seems to be effected partly by the union of the oxygen with other bodies, through which compounds are formed which are

[1] THE LANCET, July 27th and Aug. 3rd, 1895.
[2] This fact I experimentally determined in 1875. Vide Proceedings of the Royal Society, 1875, No. 157.

Digitized by Google

not magnetic, and partly also by the actual sweeping away of the oxygen in the rush of the electric current and by its attractive force. But, whatever may be the exact manner in which this change is accomplished, the absence of oxyhæmoglobin in the blood after death by electric shock is a fact beyond dispute. Thus a large quantity of deoxydised blood is at once pressed into the venous system, which by it becomes completely gorged. This engorgement of the right side of the heart appears, therefore, to take its origin partly in the great inequality produced by the current between the muscular forces in the two sides of the heart, partly in the rapidity of the process by which the blood is carried through the arterial and into the venous system, and partly in the fact that the heart loses all power of action beyond that which is due to the immediate effects of the shock.

I have stated that it is impossible to separate the physics of the cause of death from electric shock from the physics which are continuously operating to maintain the phenomena of life. I will now endeavour to prove this statement. 1. The magnetic charge in the arterial blood exceeds that in the venous blood in proportion to the oxyhæmoglobin which the arterial blood contains. 2. Magneto-electric induction determines that a current of electricity is generated in a wire by the motion of a magnet across it. 3. The coats of the arteries are composed of muscular, nervous, and fibrous structures which are brought into most intimate relation with the blood corpuscles. Now the physical laws just mentioned must obtain as certainly and as perfectly in the living body, where motion prevails naturally, as they do in inanimate matter, where the motion may be artificial. 4. But there is another great principle of the same nature which materially assists in the production of these results. The earth is a great magnet, and lines of magnetic force are constantly passing away from every portion of it. (This fact is very readily proved by connecting the two ends of a strand of wire with a galvanometer, and then sweeping the middle portion of the wire through the atmosphere. A current of electricity is generated in the wire, and the movement of the galvanometer needle is in proportion to the direction in which the sweep of the wire has been made, being greatest as the sweep has been more immediately to the north or to the south.) Thus these lines of magnetic force pass at all times through every form of matter, animate or inanimate, and every moving body, such as the blood, must of necessity collide with some of them. The nature, therefore, of the blood corpuscles, on the flow of which the energy of every living animal depends, is determined in this respect partly by the magnetic force of the oxyhæmoglobin and partly by the rapidity with which they traverse any given space and strike the lines of the earth's magnetic force; and the character and amount of the current energy originated in any living animal by the motion of its blood depends upon the nature of the blood corpuscles, and also upon the number of the corpuscles which are passing at any given moment over a nerve or other conductor of the impressions. We thus perceive how marvellously the capillary circulation is adapted for the generation of the amount of force which is required to maintain the molecular and chemical changes which are effected in the structures of those animal bodies; and we thus arrive at the physical cause of that perfect law of animal life that the vital force of every animal is in exact proportion to its requirements. So during the process of life under normal conditions the currents of energy through the nerves and the countless changes and operations of animate being take place in exact accordance with the animal's natural requirements, being all alike produced and characterised and regulated by the peculiar constitution and motion of its blood. But in the case of death by electric shock the current in proportion to its quantity is productive of abnormal and disruptive effects; for, to quote Dr. Hedley's words, "a weak current for a long time is a very different thing from a strong current for a short time, although in each instance the joules may be the same."

In conclusion I may allude to the curious fact that, though the stimulating power of oxygen is acknowledged by all, so little attention has been paid by physiologists to the study of its physical properties or of the manner in which it does its work. Now oxygen, and especially ozone, is a highly magnetic substance, and as such it has great power to disturb energy, not so much by its mechanical motion as by the lines of force which pass away from it in every direction; and in this respect it is to the air what iron is to the earth. When this fact is recognised it seems to me impossible to mistake the mode in which it does its work in the living body.

As my theory shows that natural vital phenomena are maintained by the blood corpuscles constantly inducing magneto-electric currents in the nerves, it will be seen that the extent of those pathological conditions which result from electric shock must be in proportion to the degree in which the shock exceeds the natural production of the current. Indeed, upon this principle it will be found that the variations in the pathological conditions which have been seen by different observers are to be attributed partly to the extent of the shock and partly to the physical condition of the individual when subjected to it.

I am, Sirs, yours faithfully,

Reading, Aug. 14th, 1895. RICHARD C. SHETTLE.

*** The important *rôle* assigned by our correspondent to the passage of magnetic lines of force through the body is not supported by the experimental work which has been done in submitting men and animals to the influence of the strongest available magnetic fields. If death from electric shock were simply a violent disturbance of the normal magnetic lines of flow through the body, we should at least expect marked physiological effects in animals placed in strong magnetic fields of large electro-magnets, for under these conditions the lines of magnetic flow through the body are completely altered. No such effects, however, are manifest, the man or animal placed under such conditions being completely unconscious that anything abnormal is going on.—ED. L.

"THE GRIEVANCES OF THE TELEGRAPH SERVICE CLERKS."

To the Editors of THE LANCET.

SIRS,—I have to thank you for the energetic remarks you make in THE LANCET of Aug. 31st upon the absence of any reliable official statistics concerning so important a matter as the health of the large bodies of men employed by the Post Office. As you appear, however, to be under a misapprehension concerning the reliability and typical value of certain statistics that I used in my evidence before Lord Tweedmouth's Committee I should be glad of an opportunity to explain. As the chairman of our association in London is secretary to the United Kingdom Postal and Telegraph Service Benevolent Society you will understand that we are in a position to estimate to the full the value of this society's returns. In the first place I would remind you that all the clerks employed in the Telegraph Service pass two severe medical examinations before receiving their appointments, and this is held to be so good a guarantee of sound health that insurance companies such as the North British offer to insure their lives at a reduced premium, and until this year without any further medical test. The misnamed "Benevolent" Society exacts from all entrants a declaration of health, which is supported by the testimony of another member of the society whose interest it would be, under the method of payment of premium, to exclude as far as possible all bad lives. The society, therefore, far from suffering from any "adverse selection of risks," is particularly well protected from damaged lives, and represents, as I contended in my evidence, "not the least frugal and careful of the employés." Under these circumstances I think you will be willing to admit that, pending the appearance of fuller and perhaps better statistics, those I used are certainly not *nihil ad rem*, but, on the contrary, distinctly *ad rem*. I must add that my figures are drawn from ten years' returns, not one year's, as you state. I am, Sirs, yours faithfully,

Aug. 31st, 1895. CHARLES H. GARLAND.

*** We have much pleasure in giving publicity to the above letter, but our correspondent still seems to have fallen short of establishing the authority of the Benevolent Society's statistics. If our information is correct, the rule of which he speaks requiring a declaration of health is of comparatively recent introduction, and can have had but little effect upon the mortality experience of the last ten years. The society, as we understand, was founded somewhere about fifteen years ago, and at that time and for some years afterwards, during a period of very large and rapid growth, it accepted all comers, subject only to the condition mentioned in our article of the 31st ult. In the second place, the protection supposed to be afforded by a declaration of health and the

Digitized by Google

certificate of a personal friend is of quite unproved and very doubtful efficacy. It is certainly a very poor substitute for medical examination.—ED. L.

"SUPERNUMERARY MAMMA IN A MAN."

To the Editors of THE LANCET.

SIRS,—The case of supernumerary mamma published in THE LANCET of Aug. 24th by Mr. W. F. Adams is, I think, highly anomalous. Unusual cases of this kind certainly ought to be sharply criticised before they are definitively accepted. Under these circumstances it is regrettable that Mr. Adams has not described the abnormal structure with rather more detail and precision. In spite of this, however, I have no doubt his diagnosis is correct, for it is confirmed by analogies. The condition is one of extreme rarity, for supernumerary mammary structures—so common in the thoracic region—are hardly ever found in connexion with the lower half of the trunk. A very thorough search has brought to my knowledge only eight cases of this kind. Nearly all of these were ventral in position, the redundant structures occupying the front of the abdomen in one or other of the axillary inguinal lines. However, in two cases they occupied a dorso-lateral position, as in Mr. Adams's case. It seems to me that Schultze's recent observations on the development of the mammæ in certain multimastic animals throw light on the mode of occurrence of these rare anomalies. He finds that the first mammary rudiment presents as a linear thickening of the epidermis, extending on each side from the base of the evolving anterior extremity to the inguinal region. This is the "mammary ridge," or common rudiment of the mammary glands. At first it lies nearer the dorsal than the ventral surface. In its course spindle-shaped thickenings appear, whence the mammæ of the adult are evolved. After a time the connecting strands usually disappear, and only the lenticular thickenings are left. This dorsal position of the mammary rudiments is not long retained, for migration to the ventral surface soon takes place. Although the presence of "mammary ridges" has not yet been demonstrated in the human embryo, we may, nevertheless, with tolerable certainty infer their existence from a knowledge of the facts of polymastia. It seems probable that these dorsally placed mammary structures result from abnormally developed glandular rudiments arrested while migrating to the ventral aspect of the abdomen. In females abnormally placed glands sometimes attain considerable size and secrete milk; but this is quite exceptional. In men they are invariably rudimentary. The great size of the redundant structure in Mr. Adams's case is unique and suggests gynæcomastia.

I am, Sirs, yours truly,

Preston, Sept. 7th, 1895. W. ROGER WILLIAMS.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—I beg leave to differ from the views entertained in his letter in THE LANCET of Aug. 24th by "A Specialist," "that in all cases of difficulty and chronicity ..... the 'specialist' should be consulted." Any good all-round physician or surgeon should be much preferred for many reasons; his advice would be more valued, he would be more reliable and equally, if not more, competent, especially when we are aware that the "specialist"—so-called—*does not* stick to his specialty, but attends *all* cases ushered into his consulting-room. This is not honest. Were the "specialist" to strictly adhere to the particular branch which he has chosen he would be held in higher estimation by the general practitioner and the public alike than he is at the present time. Undoubtedly we should have the aurist, the dentist, and the oculist, but this should be the limitation of specialism in medicine. When a student in Charing-cross Hospital (1869-1872) I well remember the late Dr. Silver, the lecturer on physiology, taking for his subject on one occasion, instead of his usual lecture, "Specialism," when he illustrated to his class how misleading it was and instanced the case of a young lady who perchance called at the residence of a "gynæcologist" for disease of her eyes. The "specialist" bid his fair patient to recline on his couch, when he applied the customary caustic to the os uteri. These applications were from time to time repeated, until the medical man, perceiving that his patient was becoming dissatisfied by being subjected to such a peculiar form of treatment for the complaint for which she had sought his advice, informed her that he "was most happy to say that she was now quite well." "But," quoth the lady, "the object of my visit to you was to consult you about my eyes." Many old Charing-cross Hospital men may not have forgotten this particular lecture of Dr. Silver; nay, they may probably recollect it better than his customary lectures on physiology—albeit these were both instructive and interesting.—I am, Sirs, yours faithfully,

J. FFRENCH BLAKE,
Formerly Resident Medical Officer, Charing-cross Hospital.

Aug. 30th, 1895.

To the Editors of THE LANCET.

SIRS,—"A General Practitioner," in his communication in THE LANCET of Aug. 31st, thinks that specialists have almost a monopoly of dishonesty in the profession, the dishonesty consisting in the exaggeration of the seriousness of complaints and consequent unnecessary length of treatment. My experience has been different; I have found the same dishonesty in general practitioners. Before becoming a specialist I was some fifteen years in general practice. In that time I lost various patients through the exaggeration of general practitioners—e.g., I was attending a child with the slightest of simple sore throats, when its mother was told by a neighbouring practitioner that the patient was suffering from diphtheria, according to her statement; though when I taxed the practitioner with saying this he said he used the term "diphtheritic sore throat," which was perfectly misleading and wrong. This exaggeration with the consequent prolongation of treatment is far too common, and more so, I believe, among general than special practitioners. The latter are more exposed to criticism, their work is judged by the ordinary medical attendant of patients, while "the family doctor" is autocratic in many cases without any critical supervision. One class of practitioners I have found specially given to this vice; I refer to homœopathic ones. These exaggerate systematically and recklessly; I have heard an illness called intermittent fever where there was not a sign of ague; others have been termed remittent fever, and "typhoid fever of the kind that gave way to medicine"—a gem in its way. But these are out of the pale of ordinary practice, of course. The profession might lose in money but would gain in respect if exaggeration were avoided as much as possible. It is a fruitful source of differences and disagreements among medical men and leads many to seek glory and gain at the expense of both their patients and their fellow practitioners. But I have yet to learn that it is peculiar to the much-abused specialist.

I am, Sirs, yours truly,

Sept. 4th, 1895. A SPECIALIST.

THE VOLUNTEER MEDICAL SERVICE.

To the Editors of THE LANCET.

SIRS,—I feel sure that many Volunteer medical officers will be glad to know that the representations made to the War Office authorities by Surgeon-Lieutenant-Colonel Baines and others have been successful in producing a modification of the stretcher bearers' badge for regimental stretcher bearers of Volunteer corps. I cannot, however, agree with the description of the modified badge which Surgeon-Lieutenant-Colonel Baines gives in his letter published in THE LANCET of Aug. 31st, in which he states that the groundwork is to be of the same colour as the tunic. Reading from the memorandum issued by the War Office to all commanding officers of Volunteer corps I find that the groundwork of the new badge is to be white. If it was of the same colour as the tunic the badge would be visible at a very short distance only.

I am, Sirs, yours faithfully,

R. R. SLEMAN,
Aug. 31st, 1895. Surgeon-Captain, "Artists" R. V.

DISCUSSION ON NERVE DEAFNESS IN THE SECTION OF OTOLOGY OF THE BRITISH MEDICAL ASSOCIATION.

To the Editors of THE LANCET.

SIRS,—In regard to one or two points in my introduction to the discussion on the treatment of the various forms of nerve deafness I do not appear to have made myself perfectly

Digitized by Google

clear, and I will ask you to allow me to amend with the utmost brevity the otherwise excellent report of my remarks which was published in THE LANCET of Aug. 24th. 1. The use of Delstanche's rarefacteur was advised in *labyrinthine disturbance due to sudden loud noises or explosions* for the purpose of restoring to a normal position the indriven tympanic structures and stapes. 2. Pilocarpin is not contra-indicated in *inflammation of the auditory nerve due to meningitis*, but, on the contrary, is to be recommended in recent cases in view of the fact that the labyrinth is usually implicated. 3. In the use of the galvanic current in cases of nervous tinnitus the *positive pole* should be applied to the tragus, and not the negative, as stated in your report. When one ear only is being galvanised the current should not exceed from two to four milliampères, and it is only when the current is divided between the two ears, both being treated at the same time, that it is at all advisable to double the strength of the current. 4. In my conclusions I was anxious to draw attention to the *functional element* in many cases of nerve deafness, which explained disappointments and successes in treatment otherwise difficult or impossible to account for. I should like, finally, to acknowledge my indebtedness to Professor Gradenigo for the excellent classification of the various forms of nerve deafness given in his exhaustive article in Schwartze's "Handbuch der Ohrenheilkunde."

I am, Sirs, your obedient servant,

Upper Wimpole-street, W., Aug. 30th, 1895. DUNDAS GRANT.

"OVER-OPERATING IN GYNÆCOLOGY."

To the Editors of THE LANCET.

SIRS,—The interesting letters of Dr. W. Duncan and Mr. Malcolm, published in recent issues of THE LANCET, on "Over-operating in Gynæcology" raise several questions. One of them—viz., the provision in every hospital that the patient who is to be the subject of an operation shall have the benefit of the opinion of a physician who does not operate—is of great importance and has been significantly favoured by you on several recent occasions. I agree entirely with Mr. Malcolm that all patients should have the advantage of a consultation in cases of doubt with someone not personally interested in operating. It is no disparagement of the surgeon to ask him to accept this principle. The very splendour of his achievements and the enormous improvements in his art make such acceptance reasonable. These improvements have led to operations which twenty years ago were not dreamt of. A large proportion of these operations have been justified by their results; but the alternative of success is often death within a short time, a much shorter time than would represent the chance of life from the disease for which the patient seeks treatment. The choice of such an alternative is one in which the patient can have no sound judgment. He or she is at the mercy of the surgeon. And though I should uphold the humanity of the surgeon against that of most other men I maintain that both in his interest and in that of the patient the question of operating should not rest with him, but should be determined by a consultation and the concurrence of those who have no kind of interest in the mere operation. The consultation should include, whenever practicable, a medical practitioner from the outside who knows the patient and his circumstances. But in any case it should include a colleague who does not operate and who views the matter from the non-operating side of medical work. There are, of course, many cases in which the strict application of this principle would be unreasonable, such as cases of strangulated hernia, accident, &c.; but in all doubtful cases and in all cases involving serious mutilations and loss of function its application should be imperative. It is undeniable that operations with such consequences are occasionally called for oftener than surgeons of a very conservative turn are ready to admit; but when surgery has to mutilate so seriously it should surely surround itself with the gravest sanctions. This is the clear ground of the confidence of the public in our profession and in the hospital system. The rich man and his family have this security. The poor think they have it in the nature of the voluntary hospital system, which provides, not a single officer for the treatment of all cases, but a staff of physicians and surgeons who can assist each other and check each other. This is the enormous advantage of the voluntary hospital system over mere State infirmaries or hospitals, and those who wish well to the voluntary system will respect it more and more. The surgeon who does not recognise this restraint on his unbounded freedom is not worthy of office in an institution so unboundedly trusted by the public and the poor. Trusting that these views will have your support,

I am, Sirs, your obedient servant,

Sept. 7th, 1895. OBSERVER.

"COUNTRY PRACTITIONERS AND LOCUM-TENENTS."

To the Editors of THE LANCET.

SIRS,—In the correspondence columns of THE LANCET of Aug. 31st a serious complaint is made against locum-tenents. Having on many occasions held such posts I should like to give my experience. Twelve times I have been employed, with the result that in eleven instances my services were appreciated and I was re-engaged. I was treated with every consideration, and I believe I gave the fullest satisfaction, as I am still on most friendly terms with all. My last experience was different. From an agency I received at a moment's notice an engagement at £4 4*s.* a week. On my arriving I found the practitioner had left, leaving an untidy woman to come in occasionally during the day to see if I required anything. The consulting-room (and my only sitting-room) was the kitchen, and the surgery the scullery, where, besides dispensing, this maid-of-all-work cooked what I required. As my employer left no address I was bound to remain. Upon his return, although I did my best under the circumstances, I was informed that I had neglected his work, and abuse commenced. However, I was enabled to insist on my full salary, and I left him with no regret. Doubtless, however, he represents me to my profession as an undesirable locum-tenent. I found the medical agency quite satisfied with the explanations I offered, and great regret was expressed. If general practitioners are only willing to pay a proper salary of £3 3*s.* a week good men are sufficiently plentiful to supply all they need, but indifferent pay leads to discontent, and it is not to be wondered at that serious complaints should arise. The locum-tenents are at the mercy of their individual employers, who can seriously injure them, and I regret to hear not infrequently this has occurred. Medical assistants are employed on similar dangerous ground and need protection. They are at the mercy of one man who might ruin them. I once undertook a medical assistantship. After remaining nine months I left as my principal was generally unfit to perform his duties. My reason for leaving was that I was owed four months' salary, and after frequently applying for it never received an answer and finally had to employ solicitors. By this means I obtained it, but a reference for further work was refused. However, his patients and others, amongst them medical men, gave me a most satisfactory testimonial. I had means, so I could fight him; but what would have been my position if I had been otherwise? Since I have heard his previous assistants had similiar experiences. By all means let us see if we can ensure reliable locum-tenents to be available; but equally as important is it that effort should be made to stop "the sweating system" which locum-tenents and assistants are suffering from. It dishonours our profession, lowering the prestige which it is the first duty of one and all to uphold.

I am, Sirs, yours faithfully,

Sept. 9th, 1895. LOCUM-TENENT.

MEDICAL STUDY IN GERMANY.

(BY OUR BERLIN CORRESPONDENT.)

THE following article ought to have appeared in our Students' Number, but was unfortunately crowded out owing to the great pressure on our space. The subject, however, is full of interest, not only to those still *in statu pupillari*, but to all medical men.

Academical life and the study of medicine are quite different in Germany and in England. It may, therefore, be of interest to English medical men and students to know how their professional brethren in Germany are trained, how they acquire a knowledge of medical science, and finally what they are expected to learn before they are made duly qualified practitioners. A young man desiring to enter on an

Digitized by Google

academical career with a view to becoming a clergyman, lawyer, medical man, or doctor of philosophy has to make up his mind at a somewhat early age, for he has previously to be educated in a so-called "gymnasium." These schools, whose name recalls the recreation-grounds of ancient Greece, have, however, nothing in common with the athletic sports of antiquity; in them it is the mental and not the bodily powers which are actively exercised. After at least nine years' stay in the gymnasium the aspirant has to pass a very severe examination in presence of a Government commissioner. This so-called "Abiturienten-Examen" includes Latin, Greek, French, German, mathematics, history, geography, and theology. This examination alone entitles young men to enter upon one of the above-named branches of academical study. Although it is not the purpose of the present article to criticise the method of education in Germany, it may be remarked that the training in the gymnasia, which is perfectly appropriate for the other academical careers, is not a fit preparation for medical study. Sciences such as chemistry, physics, and natural history are much more necessary for medical men than Greek is, and yet, strangely enough, the former subjects are very little or not at all taught in the gymnasia, and are not required for the final examination. There are plenty of schools (Realschulen) where these subjects preponderate, but the pupils of such schools have not the right of becoming medical students. The "Realschulen" have for a long time been striving to obtain the same privileges as the gymnasia, but their efforts have hitherto been unavailing. To become a medical student the young man has to apply to one of the twenty-one universities of the empire, show the certificate he has received from the gymnasium, and become "matriculated"—i.e., enrolled in the register of the university. Then he has to "belegen" the lectures he intends to attend—i.e., to pay the fees. In Germany no general fee is paid for medical education, but students have to pay for each lecture and for each course separately, which makes study—especially that of medicine—rather expensive. These formalities duly performed, the student, who at the gymnasium has been under very strict supervision, at once begins to enjoy absolute liberty. Nobody cares either what he does, or how he works, or whether he works at all. Only the subsequent examinations prove whether he has been a model student or has belonged to the types described by Sir J. Russell Reynolds in his genial lecture[1] as Superficialis Hurry or Vane Velox. Many of the young men in consequence of this unrestricted liberty fall into disolute habits, from which some may eventually escape, but by which others are permanently lost to society. Well-to-do students are in the habit of joining a fashionable "Verbindung" (students' association), a circumstance which does not materially assist them in prosecuting their studies. There are no precise regulations as to the method of medical study; students are entirely left to their own discretion in respect of the lectures they may attend, and a young man, if he is foolish enough, may begin his curriculum with obstetrics and finish it with anatomy or physiology. In nearly all the universities the students, however, receive printed notices at the matriculation, in which the most advisable course of study is described. Students very often go from one university to another, and it is a usual thing in Germany for a student to have been in four or five universities. Some change their universities without any special or valid reason, but others do so in order to follow the lectures of the best teacher of each subject, in which case hardly anything can be said against this custom. The course of study lasts five years and is divided into two parts. During the first two years the so-called preparatory sciences are to be learned: anatomy, physiology, chemistry, physics, microscopy, dissections, botany, zoology, &c. The university dissecting-rooms are generally very well kept and a large supply of subjects for dissection is provided. The chemical, physical, physiological, and other laboratories are often, especially in the larger universities, models of their kind. After two years' work the students may present themselves for the first examination, the so-called "tentamen physicum." This examination, which is merely theoretical, includes anatomy, physiology, chemistry, physics, and natural history. It may be taken at a later period than the close of the second year, but judicious students usually pass it before they begin the second part of medical study. The last three years are occupied with lectures and courses on surgery, materia medica, therapeutics, midwifery, and the other special branches of medical science.

[1] THE LANCET, Jan. 5th, 1895.

The difference between German and English methods is very great even in this part of the student's career. In German medical education theory is predominant even in clinical matters. At the clinical lectures the students seldom have an opportunity of examining the cases for themselves, and the medical staff do not like to see students in the hospital wards except during the lecture hours. Many rare cases may be seen and the students may hear the diagnosis explained in a very genial manner, but they are seldom permitted to approach the bed of a patient. It is true that these drawbacks do not exist in the smaller universities; they are to be found chiefly in the larger ones, and there is a remedy for them in the great number of private lectures given by "Privat-docenten" in private hospitals and out-patient departments. These private courses are often followed with much more zeal and regularity than the official lectures. Very few students are lucky enough to become clinical clerks or dressers, and as there is no formal competition it may happen that the most clever are not always chosen for these appointments. After five years' study students are eligible to undergo the "Staatsexamen," by passing which they become duly qualified practitioners. For this examination certificates are required that the candidate has passed the "tentamen physicum," that he has attended the medical and surgical clinics for two half-years, and that he has been present at four confinements. The examination consists of several different parts, called "stations," and is both theoretical and practical, the candidate being obliged to make a dissection, to perform an operation, and to examine patients in the surgical and medical wards in presence of the examiners. As no new "station" may be begun till the previous one has been passed, the duration of the examination is sometimes rather long. A candidate who has been rejected may repeat the "station" twice; if he does not pass the third time he must give up all hope of becoming a medical man. The Staatsexamen does not confer the title of Doctor, for which there is a separate examination. This may be taken either before or after the Staatsexamen, and being merely theoretical is much easier than the latter; but it is much more expensive, as the fees are very high and the candidate must have a dissertation or thesis printed at his own expense. A full description of all the mediæval formalities observed at the conferring of a medical degree would be too long for the compass of the present article. The examination for the degree of Doctor does not give a right to practise unless the Staatsexamen has also been passed. Foreigners are admitted to the former examination exclusively, and not to the latter. Some foreign medical men, however, who have got a Doctor's diploma at a German university make their friends at home believe that they are qualified German practitioners. Attempts have been made either to abolish the examination for the degree of Doctor or to combine it with the Staatsexamen, so that every duly qualified medical man may call himself M.D.; but although this arrangement has for a long time been in force in Austria and has given general satisfaction there, the universities of Germany have successfully resisted the innovation.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

Medical Man, Coroner, and Policeman.

A CASE occurred at the City Coroner's Court on the 21st ult. showing the inconvenience that a medical man may be subjected to under the relations at present subsisting between that court and the profession. The acting deputy coroner (Mr. Louis J. Aitken, barrister) informed the jury that he had received a report of the sudden death of a publican who had lived in Great Ancoats-street, and said that if the medical man who attended the deceased would sign a certificate of death an inquest might be dispensed with. He asked Mr. Macneilage, who was in court, if he would give the necessary certificate. The medical man said it was the first time he had had to appear before that court, and he wished to ask if he was to regard a verbal message as the equivalent of a formal summons. The deputy coroner said that his not having been formally summoned was purely a matter of courtesy, and that if he wished to be summoned an inquest would have to be held. In answer to an inquiry by Mr. Macneilage, who said he was speaking purely in the interests of his profession, as to whether he should be

Digitized by Google

entitled to his fee, having come in response to a verbal message—"Is my fee secured by a verbal message?" he was told: "To be enabled to give you your fee I must hold an inquest." It then transpired that the deceased had been a patient for some time, and that Mr. Macneilage had been called to him two hours before his death and was prepared to give a certificate of death; that he was awakened at half-past one the next morning by the night-bell ringing and found two policemen, who asked if he were Mr. Macneilage, and said they wanted him to come here (the coroner's court) "and speak to the death of John Ruvane." No wonder the medical man was annoyed at such an unnecessary disturbance of his night's rest, and he was reported to have used words "in the nature of a threat" towards the coroner. This the medical man repudiated: "It was not so, sir. You can understand that when a message comes through a blue-coat it is often perverted." In the end the certificate of death was given; the inquest was not held. The deputy coroner promised that in future the medical man should be formally summoned, but that his fee on this occasion could not be granted because there was no inquest. The deputy coroner, addressing the officers of the court, said that to disturb a medical man at half-past one in the morning was a most improper proceeding, and the officer had exceeded his duty. Though not without its humorous aspect this narrative shows how much annoyance and loss of time are sometimes caused by fussy and over-zealous officials attached to coroners' courts.

Death from Vegetable Poisoning.

An inquest was held on the 21st ult. on the body of a little girl six years of age who went into Gorton Park and the fields adjoining on the day but one before, and, according to her statement, ate some "green sauce." She was taken ill and died the next night. As given in the report in the *Manchester Courier*, "the medical evidence was to the effect that henbane, which grows wild, would produce the symptoms exhibited by the deceased when she was taken ill, but not the leaves of sorrel nor poisonous fungi. Death was due to eating some vegetable poison. A verdict of 'Died from misadventure' was returned." This does not seem quite satisfactory. Henbane is a comparatively rare plant, not likely to be found in Gorton Park or its vicinity, and its appearance, moreover, would probably repel rather than attract the child. The symptoms are not described. It surely would not be difficult to examine the locality carefully and ascertain what poisonous plants grow there.

Salford Union Infirmary and its Inmates.

Though the Salford guardians showed little anxiety as to the physical well-being of the children from three to nine years of age who were regaled with potato pie of which the paste, only half cooked, measured in thickness between three and four inches, before the medical officer reported against it, they must not be thought hard-hearted or only semi-civilised, for at a recent meeting of the infirmary committee the clerk read a letter from the Local Government Board adverting to one from the guardians "requesting their consent to the substitution of the word 'patient' for the word 'pauper' in the form of bed-card prescribed by the regulations for the management of the Salford Union Infirmary, and to inquire the reasons which have led the guardians to make this application." One guardian said the word "pauper" as applied to the inmates of the infirmary was detested by the board and the people of Salford. Another said he had not heard that the people of Salford wished the word "patient" used. It was a workhouse hospital and a pauper institution, and "if they removed the word 'pauper' from their rules they would open the way to persons who should be treated elsewhere." Mr. U——: "Such people come here now." Mr. S——: "They have no business to come to a place which is maintained by the rates. If a man is a pauper it is no injustice so to describe him." It is gratifying to find a sensitiveness so charming among the guardians, even though sentiment flourishes at the expense of logic; for it was moved and carried that the word "patient" should be used instead of "pauper." But how comes it, as asserted, that "patients" who are not "paupers" use this "pauper hospital"? Does this indicate another hospital abuse? The clerk said his reply would be that the guardians did not like the word "pauper," especially as it was a sick hospital, "and further that the word was not sufficiently expressive." The last reason is curious, as they seemed to think it so expressive that it must be banished from their vocabulary.

Autumnal Diarrhœa.

With the gradual increase in the ground heat there has been an increase of diarrhœa, from which young infants have suffered seriously. In his last weekly report Dr. Niven says that on the previous Saturday (Aug. 24th) "the slow-acting thermometer, suspended at a depth of four feet from the surface, attained its highest point this season—viz., 59°." In the six preceding weeks the deaths from diarrhœa and English cholera rose from 9 to 47 per week, and in that ending on the 24th ult. they rose to 59, and of these 47 were among infants under a year old. During the past eight weeks 231 deaths have been registered, "and of this number 171 had not completed their first year of life."

The Port Sanitary Authority.

An intimation has been received by the local sanitary authorities of the districts on the banks of the Ship Canal to the effect that the Local Government Board are of opinion that arrangements should be made for an investigation of the proposal that a joint board should be constituted to act as the port sanitary authority for the Customs port of Manchester. The Local Government Board consider that it would be necessary for such a port sanitary authority to come to some arrangement with the port sanitary authority of Liverpool with a view to dealing with infected ships arriving in the Mersey and intending to pass up the Ship Canal, and also with ships on which cholera may break out after they have entered the canal, and they suggest that a conference of representatives of the riparian authorities on the canal should be held to discuss the question.

Sept. 3rd.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

Death of the High Sheriff of Northumberland.

AT his house, the Chesters, on Thursday, Sept. 5th, died Mr. N. G. Clayton, the High Sheriff of Northumberland. On Sept. 5th, 1751, the foundation stone of the infirmary at Newcastle was laid, an ancestor of the deceased gentleman, Mr. W. Clayton, being sheriff. Ever since its foundation the Clayton family have taken an interest in the institution, and Mr. N. G. Clayton was no exception, he having been on the committee of management for upwards of twenty years and always an active and liberal supporter of the charity. The Claytons are an old Yorkshire family, and there is no name more respected than theirs in the town of their adoption. It may well be so, for there is no charitable institution in Newcastle with which the name has not been for long associated.

Site for a New Infirmary, Newcastle-upon-Tyne.

This question seems no nearer settlement than it was four or five years ago. The governors have asked the civic authorities to give them, or to assist them in procuring, a new or an enlarged site; but so far, though the city council expresses sympathy and says it will do what it can to assist, both propositions made by the infirmary authorities — first for a new site on the Leazes, and secondly for a portion of the cattle market to augment the present site—have been refused in the one case and reported upon adversely in the other. It seems that the cattle market in Newcastle-upon-Tyne cannot be moved out of the centre of the city, though an equally convenient site could readily be found for it on ground belonging to the town, because there are vested interests which would suffer. There are many reasons, however, why the cattle market should be moved. The driving of droves of cattle through the main thoroughfares of a populous city on two or three days a week is inconvenient and not free from danger—indeed, many serious accidents have been treated in the infirmary owing to foot-passengers being gored by bulls. Sooner or later, there can be no doubt, the cattle market will be moved, and should, unfortunately, a prominent citizen be injured by an excited beast perhaps the transfer would be sooner than later. In another month the city council will consider the report of the Finance Committee, presented on Sept. 4th, recommending that no ground should be given to the infirmary for the purpose of enlarging the present site—a report characterised by Mr. Alderman Richardson as "a very one-sided report."

The Newcastle-upon-Tyne City Lunatic Asylum.

The annual report of the above has just been issued. In

Digitized by Google

it the commissioners express themselves as well satisfied with the condition of the patients and of the wards, and draw attention to the fact—eminently satisfactory—that "no mechanical restraint" has been employed and only one patient placed in seclusion during the year. The daily average of patients has been 463, of whom 47 were epileptics. Sixty per cent. of the males and 71 per cent. of the females had been usefully employed during the year. Dr. James Callcott, the medical superintendent, states the percentage of recoveries to have been 33·6; the deaths were 41, a percentage of 8·8. The coroner held an inquest in one instance only, and a verdict of "Death from natural causes" was returned. The enlargement of the institution is being rapidly pushed forward.

Death of Mr. Chas. Mitchell, LL.D.

Dr. Mitchell, who has just died at Jesmond Tower, has left an enormous fortune of some £2,000,000, all made by him on Tyneside. Dr. Mitchell built one of the most sumptuous churches in the North of England, near his residence, and presented it, together with a fine house for the clergyman, to his diocese, spending some £31,000 in the process. He was also munificent in his gifts to the University of Aberdeen, of which university he was an honorary graduate and had been an under-graduate. By his will the cottage hospital at Walker, built and given by him to the town, receives a legacy of £1000 free of legacy duty.

Entertainment to Nurses.

Sir George and Lady Trevelyan, of Wallington Hall, Northumberland, entertained on Tuesday, Sept. 3rd, a party of nurses from the Royal Infirmary, Newcastle-upon-Tyne. A saloon carriage conveyed them from the Central Station at 8.20 A.M. to Scots Gap Station, where carriages from Wallington Hall awaited their arrival. On reaching the Hall Sir George and Lady Trevelyan received them most kindly, and showed them over the house, with its most interesting collections of paintings and old china. Luncheon was provided at one o'clock, and the guests afterwards spent a very pleasant time in the grounds and gardens, returning to tea in the Hall. Each nurse was presented with a bunch of lovely flowers, and also with a photographic view of the interior and exterior of the house; and, having spent a most enjoyable day, they all returned at 6.30 P.M.

The Dean of Durham, the Very Rev. Dr. Kitchin, has returned much improved in health, and has undertaken to distribute the prizes to successful students at the opening of the University of Durham College of Medicine at Newcastle-upon-Tyne next month.

Newcastle-upon-Tyne, Sept. 9th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Matriculated Students in Scotland.

A NEW regulation with regard to matriculated students under the Universities (Scotland) Act, 1889, has just been published, and is to the effect that no person shall be deemed to be a matriculated student in any Scottish university or shall enjoy the privileges of a matriculated student unless in addition to paying the matriculation fee he is enrolled as a student in attendance in one or more classes of the university and pays fees entitling him to such attendance.

Re-election of Mr. Finlay, Q.C.

Mr. R. B. Finlay, Q.C., has been re-elected Member of Parliament for the Inverness Burghs. Mr. Finlay is a graduate of medicine of Edinburgh and comes of a medical stock, his father having been a practitioner in the neighbourhood of Edinburgh, and he has a brother who is also in practice.

Reported Outbreak of Glanders in Glasgow.

The local health authorities have recently been considering some rather sensational rumours with regard to the presence of glanders in the city. Professor McCall of the Veterinary College has been able to assure the authorities that the rumours are considerably exaggerated, and that every reasonable precaution has been taken to protect the public health. It has been decided to send a detailed statement of the facts to the Board of Agriculture.

West of Scotland Convalescent Homes, Dunoon.

At the annual meeting of this institution the secretary reported that the homes during the year had accommodated 3750 convalescents. The gross expenses per week for each inmate had been 10*s.* 10*d.* In their statement the directors acknowledge the receipt of £500 from Mr. Alex. Sinclair of the *Glasgow Herald*, and a valuable contribution to the library from Sir James King. The Rev. Dr. Donald Macleod, in speaking in support of the annual report, suggested that the well-being of convalescents on leaving hospital might be still further consulted by the conversion of a large ship into a home. This might be anchored off the Island of Arran and would secure for invalids all the benefits of a sea voyage.

The Purification of the Clyde.

The Glasgow Police Commission have decided by a large majority to apply to Parliament for power to proceed with a scheme for dealing with the sewage from the northern part of the city. The estimated cost of the scheme is £600,000.

New Hospital for Infectious Diseases, Glasgow.

The memorial stone of the new Corporation Hospital at Ruchill Park, in the north-west portion of the city, was placed in position on the 30th ult. by Lady Bell, the wife of the Lord Provost. On the invitation of the corporation a large number of medical men and leading citizens were present, but the ceremony was somewhat marred by the extremely wet weather. At the luncheon which followed the ceremony the toast of the medical staff was responded to by Dr. Johnstone, the superintendent of the Fever Hospital at Belvidere, and by Dr. A. K. Chalmers, one of the medical officers of health for the city. The senior medical officer of health, Dr. J. B. Russell, has been laid aside by illness for some months, but his numerous friends will be glad to hear that he is now convalescent and will shortly resume his duties.

Hospital and Nurses' Home for Coatbridge.

The late Mr. John Alexander (a partner of the firm of William Baird and Co., Limited, iron and coal merchants) has in his will left a sum of £30,000 to build and endow a hospital for the treatment of medical and surgical cases in the town of Coatbridge. The institution is to be called the Alexander Hospital, and in connexion with it there is to be a home for trained nurses, who are to work amongst the sick poor of the town and neighbourhood.

Sanitary Association of Scotland.

This association met for its annual congress at Greenock in the last week of August under the presidency of Sir Michael R. Shaw-Stewart, who in his opening address reviewed recent sanitary progress, more especially in rural districts. Amongst the papers read to the association were the following: The Rates of Mortality in Scotland in relation to Sanitary Progress, by Dr. Matthew Haig, Professor of Medical Jurisprudence and Public Health in Aberdeen University; Infectious Diseases in Scotland and Hospital Isolation, by Dr. A. Campbell Munro, medical officer of health, Renfrewshire; the Diseases of Occupations, by Dr. Nasmyth, Ayr; Diphtheria, by Dr. Leslie Mackenzie, Leith; and the Housing of the Submerged Tenth, by Bailie Chisholm, Glasgow. The discussion of these and other papers was taken part in by a large number of the members, who were also given abundant opportunities for seeing the beauties of the Clyde and for cultivating those social developments for which, at least in part, annual conferences exist.

Aberdeen University: the Inaugural Celebrations.

At a meeting of the Senatus held at the end of August it was agreed that, owing to the lamented death of Mr. Charles Mitchell, LL.D., Newcastle-on-Tyne, the ceremonial on the inauguration of the Graduation Hall &c. should be of a comparatively simple character. It has now been agreed that there shall be only one series of ceremonies, not extending beyond two days, and that the date thereof shall be postponed till December out of respect to the memory of the deceased. The Students' Union will be opened without any formal ceremony at the beginning of the present session. Unfortunately, this postponement will prevent the celebrations falling within the period of civic office of Lord Provost Stewart, to whose advocacy and support the progress of the extension scheme has been so largely due. The great "historical window" in the new Graduation Hall is now completed, the finishing touch being put to it last week by Colonel Crawford, who, as the trusted financial head of the great firm of Lord

Digitized by Google

Armstrong, Mitchell, and Co., has been for half a century Dr. Mitchell's valued colleague. The window, which costs upwards of £2500, illustrates the history of the college by a series of brilliant heraldic and portrait representations of the more notable figures connected with the university. It measures 32 ft. high by 28 ft. broad, and comprises four tiers of panels. The two upper tiers are filled with the arms of George Keith, fifth Earl Marischal, founder of the college; the city of Aberdeen, joint-founder; and of the eleven noblemen who succeeded the founder as chancellors of the college. The second tier consists of three groups of five panels each. The group to the left is decorated with the arms and figure portraits of representative alumni prior to 1700; the group to the right with those of alumni of the period 1700–1800; and the central group with those of alumni of this century, especially of gentlemen prominently associated with the university in the present day. The fifteen panels of the lower tier have the armorial bearings of thirty benefactors of the college, covering a period of nearly 250 years.

The Extensions at Marischal College.

The Sites and Plans Committee of the University Court have approved of plans submitted by Mr. Mackenzie, A.R.S.A., of the tower to be erected at the extremity of the extended north wing of Marischal College fronting Broad-street. The plans show a lofty and graceful structure of dressed granite.

Monument to a Philanthropic Aberdeen Practitioner.

There has just been erected by public subscription in the interior of New Porthill School, Gallowgate, Aberdeen, a mural tablet of Gothic design to commemorate the late Dr. Reith's services in that populous though poor district. The memorial is in grey and red granites, and was designed and executed by Mr. Arthur Taylor, sculptor, Aberdeen. The inscription on the panel is as follows: "To the memory of Archibald Reith, M.D., founder and superintendent of this school, who entered into rest 30th December, 1894, in his 58th year. Consecrating in early manhood the gifts of a rich and generous nature to the service of his Lord, he devoted himself for thirty-four years to the spiritual and moral well-being of the young people of this neighbourhood with single-hearted enthusiasm and self-sacrificing love. By his exertions and according to his plans this building was erected in 1876.—He saith unto Him, 'Yea, Lord, Thou knowest that I love Thee.' Jesus saith unto him, 'Feed My lambs.'"

The Health of the City of Aberdeen.

The following is the return of zymotic diseases notified last week: measles, 1; scarlet fever, 22; diphtheria, 1; whooping-cough, 51; erysipelas, 6; total, 81—being 42 cases more than in the preceding week. The rise is due to an increase in scarlet fever and whooping-cough.

Sept. 7th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Rotunda Hospital.

THE ceremony in connexion with the opening of the new wing of this hospital, which was announced to take place on Aug. 30th, has been postponed.

Reorganisation of the Army Medical Staff.

An effort to revive the old and vexed question of the position and titles of the Army Medical Staff is now being made in Dublin, whence so many of the present corps of army surgeons have come. A letter appeared on Sept. 2nd addressed to the editor of the *Irish Times*, in which attention is called to the fact that military surgeons have recently been honoured by very frequent mention in despatches, notably in the case of the Chitral campaign, and that they can now claim to have received "the largest proportion of Victoria Crosses in the service." The writer suggests among other changes the following:—The formation of a Royal Medical Corps and the complete control of it by army medical officers. The abolition of the superfluous titles of Surgeon-Lieutenant, Surgeon-Captain, &c., and the substitution instead of Lieutenant, Captain, &c., of the Royal Medical Corps. There is no doubt that army medical men have many real grievances which should be removed. State service, however, is very popular in Dublin. There was a time when, on the other hand, the Medical Department of the Royal Navy was eagerly sought by young surgeons recently qualified at our University and schools. Now, the improved status of medical men in the army and the high-sounding though curious and cumbersome titles which they by persistent agitation have acquired have changed all this. The naval medical authorities have expressed surprise at the small number of candidates who have presented themselves at their examination of late years; but, apart from the causes which have been mentioned, there are other reasons which tend to induce young medical men from here to choose the army in preference to the naval medical service. Naval medical officers, and, indeed, naval combatant officers, are but little known here, and accordingly hold a much less well-recognised social position than their brethren of the army. There is, of course, a naval guardship at Kingstown, but, on the other hand, there are always crack regiments stationed here and at the Curragh.

Queen's College, Belfast: The President's Report: the Students' Union.

The President of Queen's College, Belfast (Dr. Hamilton), has recently presented to Her Majesty his annual report for 1894–95. During the past session 117 students entered the college for the first time, and the total numbers enrolled show that the medical school contributes the great majority. In the faculty of arts there were 145 students, in law 26, in engineering 13, while in medicine there were 212; 15 ladies attended the college. Of the students in attendance 336 came from Ulster, and as regards age 230 were over twenty-one and 156 younger. The President referred with great regret to the death of Dr. McCosh, President of Prince Ion College, New Jersey, U.S.A., who for a period of seventeen years occupied the chair of Logic and Metaphysics in Queen's College, Belfast. Queen's College attains its jubilee this year, and the council have resolved that it shall be fittingly celebrated.

The plans for the Students' Union have been prepared by Mr. Robert Cochrane, F.R.I.B.A., F.S.A., and promise a building which will be in every respect well adapted for the purpose aimed at. Tenders have been accepted, and the total cost, with furnishing, will be about £7000. The building will be commenced forthwith, and it is expected it will be ready for occupation by students at the beginning of the session after next.

Death of a Workhouse Fever Patient.

The guardians of the Ardee (county Louth) Union have just received from the Local Government Board their decision in reference to the death of a patient in the Fever Hospital. The Local Government Board say they cannot but regard this case as discreditable and as tending to shake confidence in the management of the Fever Hospital. The patient whilst in a state of delirium escaped from the Fever Hospital at 3 o'clock in the morning with nothing on but his shirt, and was not brought back until almost 11.30 A.M. The exposure to which he was subjected must undoubtedly have accelerated his death, which occurred next day. The Local Government Board consider that the blame in the matter rests with the master and porter of the workhouse, and request the board of guardians to call upon these two officials to resign. It would appear that though warned by the medical officer and nurse the master took no trouble to procure paid assistance from outside the workhouse when he was, as he states, unable to procure it inside. This painful case will certainly tend to strengthen the hands of those who have been recently criticising the provision made for the care of the sick poor in Irish workhouses.

Death of a Lunatic in Lisburn Workhouse.

An inquest has been held in reference to the death of a woman forty years of age who was admitted on Aug. 23rd to the Lisburn Workhouse with acute mania, and who died from bronchitis, syncope, and weakness on Aug. 28th. The coroner said, in addressing the jury, that such cases should be removed from workhouses to asylums, which were the proper places for them and had the proper accommodation for treatment. The jury returned a verdict of "Death from syncope of the heart, the result of weakness and mental excitement," and added that in their opinion "the lunatic department on the female side of the workhouse is in a most wretched, insanitary, and crowded state, and unfitted in every way for the reception of the weak-minded poor who are at present placed there."

Death of Mr. Mark Anthony Savage, M.B. Edin., Newry.

I regret to announce the death of Dr. Savage of Newry,

Digitized by Google

which occurred on Aug. 29th. It seems that about three weeks ago he went to Wigton, Scotland, to do duty for a brother medical man, an old school friend, and while there in the course of his duty he cut his hand. He thought the wound was healing and returned to Newry on Aug. 28th. He was out that day, but during the night alarming symptoms set in, and, despite every care and attention on the part of Dr. Crosslé and Mr. Smartt, he died from blood poisoning the next day. Deceased, who was thirty-seven years of age and was a graduate of the University of Edinburgh, had served for five years as surgeon on board one of the warships of the Chilian Government, and he came recently to Newry to take up the practice of his late father.

The Battle of the Clubs at Cork.

At a meeting of the Cork United Trades' Association held on Aug. 29th the president alleged that the members of the Cork clubs are systematically boycotted by the city hospitals. He carefully avoided giving details, though he promised they would be forthcoming if the hospital authorities should think fit to make inquiries on the subject. He hinted that the corporation grants might be withheld, and suggested to the mechanics of the city to think twice before they contributed to the Hospital Saturday Fund. After mentioning that one club patient had received "an unsatisfactory reply" at the South Infirmary and that another was refused admission at the North Infirmary he treated his audience to a peroration, in which he asked, Was "such traffic in human lives to be tolerated"? The president happens to be a member of a benefit club, and his anxiety to attack the Cork medical men apparently made him forget that he was addressing a body of trades-unionists. However, no time was lost in reminding him of the fact. One of the members, Mr. Murphy, said that as far as he understood the hospitals were not boycotting anyone, and if he desired admission to a hospital he could go in, and he added that as trades-unionists they should not recognise the imported medical men. Mr. Kelleher considered it was unfair for the president to bring forward such a matter at all, it having been ruled out of order that night week. Mr. Harty considered that they should not entertain the subject at all, and a resolution which he proposed to that effect was carried by twelve votes to seven. A couple of days later leading articles on the subject appeared in two of the local papers, and though the phraseology was different the ideas were precisely the same. The whole tone was, "we can hardly believe the staffs of the hospitals acted in the manner stated, but it looks uncommonly like it." So far I have been able to make inquiries with regard to two of the principal hospitals referred to, and I find that club patients have been freely treated at these institutions. No doubt club patients have in some instances been refused admission, but solely because they were considered to be cases unsuitable for treatment in a general hospital. This incident is regarded by the Cork medical men as an indication that the clubs are sorely mortified by the falling through of the recent negotiations. The *personnel* of the club delegates at the mayor's conference was remarkable. No less than five of them were Oddfellows. One was secretary to a lodge and corresponding secretary to the several lodges in Cork. Another was secretary to a club which embraces numerous rich members, but the poorer clubs had no direct representatives. Hence it is easy to understand why the delegates made such a vigorous fight for the retention of existing members in receipt of over £200 a year. I hear every day of club members feeing private practitioners, and it is only natural to expect that, under the circumstances, the clubs will become gradually decimated. The richer members know this, and they are very anxious for a compromise which will still secure for them medical services at a comparatively cheap rate. However, the Cork profession will not desist till they compel these gentlemen to pay adequate medical fees in the future. When the usual half-yearly grants to the North and South Infirmaries were being considered by the corporation reference was made to the allegations of the president of the Cork United Trades' Association, to the effect that patients were refused admission to those hospitals because they belonged to benefit clubs. Some members of the council voted in favour of the money being withheld pending an investigation, but the Mayor pointed out that the statements were *ex parte*, and ultimately the grants were sanctioned. The governors of the South Infirmary having requested the president to supply further particulars, he gave the name of only one patient, who, on inquiry, was found to suffer from paralysis agitans, and in accordance with a rule of the hospital could not be admitted because his case was incurable. The secretary had absolutely no knowledge as to whether the patient belonged to a benefit club or not, and, moreover, informed the governors that several club patients have been treated in the hospital. The authorities of the Mercy Hospital have already contradicted the statements with regard to the institution under their control, and the governors of the North Infirmary will probably not be slow to follow their example.

Viceregal Visits to Hospitals.

Her Excellency the Countess Cadogan has recently visited many of the Dublin Hospitals, including the Adelaide, with its children's ward and its "nurses' home"; the Children's Hospital, Temple-street, under the charge of the Sisters of Charity; the Dublin Orthopædic Hospital, where her Excellency was conducted to the gymnasium, with which she was much pleased; and the Rotunda Lying-in Hospital, which is, of course, one of the largest of its kind in Europe, if not the very largest. Lady Cadogan was conducted through the wards of this great maternity hospital and graciously promised to attend the opening in November of the new wing, which she considered "would be a valuable addition to what is now one of the finest institutions of charity in the city of Dublin." Her Excellency has, indeed, been indefatigable in her wish to extend her patronage to the medical charities of Dublin. She drove out on Saturday accompanied by Lady Betty Balfour and Captain Algernon Peel to Blackrock to visit the Convalescent Home at Linden, with which she expressed herself as being much pleased. The institution is managed by a community of nuns, and is, with the exception of some sixteen beds which are endowed by the Mullen's Fund, dependent on the voluntary contributions of the public for its existence.

School of Medicine, University of Dublin.

The prospectus for the coming winter and summer sessions of 1895–96 has recently been issued. The Regius Professorship of Surgery has not been filled since the lamented death of the late Sir George Porter. The position of University Anatomist is now occupied by Dr. Charles Ball, in succession to Dr. St. John Brooks, resigned. Mr. Alexander C. O'Sullivan, M.D., F.T.C.D., has been appointed to the long-vacant University Lectureship on Pathology, and he will lecture on pathology thrice weekly during the winter, and conduct a class of "Practical Pathological Histology" during the summer session. Dr. Edward H. Taylor now occupies the position of University Examiner in Anatomy.

Medical School of the Royal College of Surgeons in Ireland.

"A Guide to Medical Students," containing much useful information as to the course they should follow in preparing to qualify for the diploma of the Conjoint Board of the Royal Colleges of Physicians and Surgeons in Ireland and the expense they must incur in the shape of fees &c., has recently been published by the Royal College of Surgeons. From this it will be seen that the school buildings there have recently been reconstructed, the capacity of the dissecting-rooms much increased, while special pathological, bacteriological, public health, and pharmaceutical laboratories have been fitted with the most modern appliances to facilitate the progress of students of medicine. Among novel features is to be seen the announcement that a luncheon-room is now provided, while special rooms have been set apart for the convenience of lady students.

Sir Patrick Dun's Hospital.

Her Excellency the Countess Cadogan recently paid a private visit to this hospital, and was conducted round the wards by Miss Huxley, Dr. Walter Smith, and Dr. C. B. Ball, the governors of the hospital being represented by the Rev. Dr. Haughton. The annual prospectus for the session 1895–96 has just been issued, the only changes in it being the vacancy in the position of consulting surgeon, caused by the death of the late Sir George Porter, and the appointment of Dr. Edward H. Taylor on the surgical staff in succession to Dr. St. John Brooks, resigned.

Maguiresbridge Dispensary.

At a meeting of the Maguiresbridge Dispensary committee on Sept. 4th Mr. Aiken of Kesh was elected medical officer.

Sept. 10th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

Death of Professor Luigi Galassi.

WE have lost the dean of our medical faculty in Dr. L. Galassi, Ordinary Professor of Special Pathology in the University, who died on the 31st ult. after a long and painful cardiac disease. Dr. Galassi had a distinguished record as a man of science and as a teacher. He was for many years President of the Accademia Medica di Roma, a member and Vice-President of the Consiglio Superiore di Sanità, Vice-President of the Red Cross, Rector of the University, and President of the Faculty of Medicine. His extra-professional honours were hardly less conspicuous. He was Commendatore of the Crown of Italy and Saints Maurice and Lazarus, Knight of the Crown of Prussia, and the holder of many other decorations of a scarcely inferior order, Italian and foreign. But his life-work was in the clinical ward, the dead-house, the laboratory, and the lecture-room, where his scientific accomplishment and winning powers of exposition and persuasion made him a universal favourite with pupils and colleagues alike. The University displayed its banner, half-mast high and draped with mourning, as soon as his death was made known, and on the 1st inst. a public funeral took place, the pall-bearers being Signor Constantini, Under Secretary of State in the Ministry of Public Instruction; Dr. Panizza, Sanitary Assessor of the Municipality; Professor Monaci (representing the Rector of the University, absent through illness); the Commendatore Silvestrelli, delegate of the Red Cross; the Senator Dr. Todaro, Professor of Anatomy (deputed by the Accademia Medica); Colonel Martinelli of the War Office; Professor Ballori; and Dr. Ciccolini, representing the Medical Aid Society of the Practitioners and Pharmacists of the Province of Rome. The long train of mourners which followed included the leading physicians and surgeons of the city and a numerous body of students, mainly of the medical faculty.

The Petrifaction of the Human Subject.

This, like the cognate art of embalming, is almost an Italian specialty, in which the past master was the naturalist Dr. Girolamo Segato, whose marvellous feats in petrifying the dead and preserving their features and even their complexion for all time are *en évidence* in the Florentine Museum, of which they constitute one of the chief attractions. A highly successful example of his skill—the petrified head of a young woman who had died from pulmonary tuberculosis—had been known to exist, but for sixty years, in spite of every effort to trace it, it was nowhere to be found. His grandsons, anxious to recover this, the last, and perhaps the most striking, specimen of his art, have been indefatigable in the search for it, but without avail until a few days ago, when by the merest chance they alighted on it in Bavaria and immediately took steps, with no small difficulty and outlay, to restore it to the treasures of Italian anatomical science. The numerous "changes of address" it had undergone in those sixty years have done it no appreciable damage; indeed, its preservation is so perfect that in the words of Signor G. Segato fù Andrea, who announces the discovery, "its luxuriant blonde hair, quite wavy and soft, is like that of a living person." Its present provisional place of custody is at Pieve di Cadore, whence it will be transported in a few days to Belluno and kept on view for the inspection of the scientific public, after which it will go either to Florence or, more probably, to some other medical school less rich in specimens of Dr. Segato's peculiar and weirdly fascinating *métier*.

A Health Resort for Rome.

This is no other than Rocca di Papa, 750 metres above the sea level, situated on the southern rim of the Alban Mount, high above all malarious influence. In fact, those who resort to it even when labouring under palustral fever make a speedy recovery from the disease. The mortality of its inhabitants taken from the sanitary returns between 1884 and 1894 has been not more than 18 per 1000, while that of Italy during the same decennium averaged 26·17 per 1000. The air is peculiarly fresh and exhilarating, the walks and mountain paths well shaded, and as for the water (quite recently analysed), it is among the best *acqua potabile* in Italy. The mineral salts are in scanty proportion; ammonia, nitrous acid, and sulphuric acid are wanting; nitric acid exists only in traces; and organic substances are "conspicuous by their absence." Bacteriological examination confirms this favourable finding, while the supply is as abundant as it is pure. The mean temperature may be inferred from the following table, compiled by Professor Lucchesi, director of the Meteorological Observatory on the Alban Mount:—

Average Degrees of Temperature (Centigrade).

—.	Ordinary.	Minimum.	Maximum.
June	15·64	12·22	19·41
July	19·53	15·96	23·24
August	19·39	15·97	23·31
SUMMER AVERAGES...	18·19	14·72	21·29
September	15·89	13·13	19·12
October	11·25	8·60	13·81
AUTUMN AVERAGES...	11·45	8·90	14·15

And yet it is only now that steps are being taken to utilise this charming upland village for the benefit of the Roman population, whether as convalescents or in quest of summer quarters. A good railway and good hotel and *pension* accommodation will shortly, I understand, be made *faits accomplis* and Rocca di Papa be restored to the place it had in Republican and Imperial times as one of the "lungs" of the city, not less conducive to physical than to moral rehabilitation.

Queen Margherita and the Italian Hospital in London.

There is on its way to the Italian Hospital in London another token of the interest taken in the institution by the Queen of Italy. It is a photograph of Her Majesty, sent by Queen Margherita herself and bearing the following autograph inscription: "Possano gl'italiani raccolti in questo luogo ritrovare sotto le benefiche ali della carità la patria, lontana nello spazio ma sempre presente nel desiderio del cuore.—Margherita." (May the Italians gathered together in this place under the beneficent wings of charity be able to find once more their native land—distant, indeed, in space, but ever present in the heart's desire.—Margherita.)

A New Health Resort at Vallombrosa.

As I close this letter I hear from Florence that that city is about to have a much-needed adjunct to her medical resources in the form of a new health resort at Vallombrosa. At the instance of his Excellency Signor Barazzuoli, Minister of Agriculture, and of the Director-General under the same department of Government, there will be established at this salubrious and picturesque station in the Apennines an institution for convalescent patients. Its design and construction have been committed to the experienced hands of Dr. Giuseppe Corradi, Professor of Clinical Surgery in the Florentine School, whose competence in all such undertakings is universally conceded. A pure and abundant water-supply will, as a primary requisite, be immediately provided, and every appurtenance, internal and external, for the use of the resident staff and the patients will be in readiness within a year, the period assigned for the completion of the work. In connexion with the establishment Professor Corradi has also undertaken the enlargement and reappointment of the local hotel, well known as the "Croce di Savoia."

Sept. 7th.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

Cholera in Galicia.

SOME three weeks ago the newspapers announced an outbreak of epidemic diarrhœa among the soldiers in the garrison of Przemysl, in Galicia, and some fatal cases of Asiatic cholera are now reported from Tarnopol. This outbreak is attributed to the impurity of the water in the river Sereth and to infection from the adjacent parts of Russia, where epidemic cholera has of late years prevailed. It has not died out there; it has only been dormant, and has recently manifested itself in a sporadic form in Podolia and Volhynia. The Government has sent sanitary experts to advise as to the necessary measures to be undertaken.

Antistreptococcic Serum.

Dr. Marmorek has published in the *Medicinische Wochenschrift* further details on the streptococcus and the serum

Digitized by Google

which is not only curative in diseases caused by this microbe but prophylactic as well. As a result of many experiments it has been shown that this coccus may be cultivated in a mixture of two parts of human serum and one part of peptonised bouillon and will maintain its virulence, which may be augmented by a continual passage through the system of rabbits, a dose of 0·000,000,000,01 c.c. (hardly containing more than one streptococcus) being sufficient to kill a rabbit in a short time with symptoms of septicæmia. Some investigators have already succeeded in immunising animals against this microbe by both sterilised and living cultures, the latter producing a higher degree of immunity. The serum is to be taken not earlier than four weeks after the last injection. Its prophylactic energy may be judged from the quantity necessary to immunise a rabbit weighing from 1500 to 1800 grammes against a tenfold quantity of the lethal dose. The serum has been used in numerous diseases caused by the streptococcus—namely, erysipelas (423 cases with a mortality of 3·87 per cent.), angina, phlegmon, and other septic processes. The patient's general condition was advantageously influenced, the temperature being lower and the redness, swelling, and albuminuria being less. In the gravest cases a dose of 20 c.c was injected, followed by 10 c.c. next day, the maximum dose amounting to 120 c.c. Among seven cases of puerperal fever no death occurred, whereas it was given without benefit in cases which were complicated with bacterium coli. Very gratifying results have also been obtained in cases of phlegmon and of pseudo-membranous angina caused by the streptococcus.

Suicide in Vienna.

According to returns made by the Central Statistical Commission the number of suicides in Vienna during 1889-1893 amounted to 1254, equivalent to a rate of 3·2 per 10,000 of the population. Among the corresponding returns of some other Continental towns may be mentioned Paris with 3·6, Brussels with 3·29, Berlin with 2·98, Munich with 1·98, and Breslau with 3·91 per 10,000 of the population. During the seven preceding quinquennial periods 360 cases of suicide occurred in 1854-1858, 367 in 1859-1863, 565 in 1864-1868, 631 in 1869-1873, 1020 in 1874-1878, 1129 in 1879-1883, and 1196 in 1884-1888. Among 100 cases of suicide 77 were men and 23 were women. Adolescents appear to have every year more frequent recourse to this method of terminating their real or supposed miseries, the highest rate being registered at the age of sixteen to twenty-five years. Among 100 suicides 32·5 ended their days by hanging, 23·5 by pistol shots, 22·4 by poisoning, and 5·8 by drowning. With respect to the poisons, cyanide of potassium was resorted to in 12·7 per cent. of the cases, caustic lye in 22·7 per cent., phosphorus in 26·1 per cent., and sulphuric acid in 7·2 per cent. As for seasonal distribution, the proportions were: in January 8·5 per cent., in February 7·6 per cent., in March 8·9 per cent., in April 9·1 per cent., in May 10·5 per cent., in June 8·7 per cent., in July 8·1 per cent., in August 7·2 per cent., in September 7·4 per cent., in October 8·3 per cent., in November 7·8 per cent., and in December 7·9 per cent.

The Inebriates Bill.

The Minister of Justice has at last submitted the Inebriates Bill to Parliament. The medical profession has for a long time urged that the existing laws for dealing with inebriates should be strengthened; it has also long advocated the absolute exclusion of inebriates from lunatic asylums, where they are disturbing elements by reason of their mental superiority. Preceding Governments did not attend to these recommendations; on the contrary, in Galicia, which is a hotbed of alcoholism, it has not infrequently happened that clergymen and other persons who commented on this vice have been reprimanded on the ground that the interests of the distillers might thereby be injured. Thanks to the endeavours of the present Government this difficulty is now apparently overcome, and Austria will have asylums for inebriates such as already exist in Great Britain, in the United States, in Sweden, and in Switzerland. According to the Bill these asylums are to be established either by the State, the province, or the municipality. Detention may be either voluntary or compulsory, but voluntary inmates will not be allowed to leave the asylum at their own option. The compulsory cases will include those who have by their drunkenness brought themselves more than thrice into the police-courts within the last year, drunkards convalescent from mental disease, and those persons who without any mental disease endanger their own interests and those of their family by drunkenness. The inebriates are to be discharged in the event of a reversal of their sentences or after a three years' residence in the asylum. They may also be liberated upon trial after the lapse of one year. The Bill, moreover, provides for punitive measures against attempts to frustrate the successful working of the asylums.

Lunacy Statistics in Lower Austria.

According to the report of the Provincial Government of Lower Austria, the number of lunatics at present amounts to 2636. Of these, 932 are in Vienna, 196 in Langenlois, 541 in Ybbs, 487 in Kierling, 407 in Klosterneuburg, and 73 in Mödling. Among the 498 male patients detained in the Vienna Asylum there are 60 officers, 1 lawyer, 3 architects, 5 writers, 5 professors, 2 clergymen, 7 merchants, 340 workmen, 19 farmers, 33 servants, 2 foresters, and 21 of no definite occupation.

Sept. 4th.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

The Jenner Centenary in Russia.

IN connexion with the centenary of the introduction of vaccination, which is to be commemorated next year,[1] the Russian National Health Society offers four prizes for the best literary work upon small-pox and vaccination, under the following conditions. The essays may relate either, firstly, to the general question of small-pox and vaccination, or, secondly, to the technique of vaccination itself. Under the first heading are mentioned: (*a*) text-books on vaccination; (*b*) historical, medico-geographical, and medico-statistical works; (*c*) clinical, pathological, bacteriological, or chemical investigations; and (*d*) popular works on the utility of vaccination. Under the second heading are mentioned: (*a*) essays on the preparation of vaccine lymph and the best methods of preserving and transmitting it; (*b*) new suggestions as to the best forms of instruments used for vaccinating man and animals; and (*c*) suggestions for a model vaccination institute. Authors are not limited to any one of the above, and other aspects of the subject may be treated of in the essays. The essays may be written in either Russian, French, German, or English; they may be in manuscript or print, but must not have been printed anterior to May 2nd (14th), 1894. They must be sent in not later than March 2nd (14th), 1896, addressed to the Council of the Russian National Health Society, Dmitrovski Pereoulok No. 15, St. Petersburg. Authors may sign their own names or may write over a pseudonym, in which case they must send their own names in a sealed envelope. The first prize will be a gold medal and 1000 roubles (100 guineas approximately); the second and third, gold medals; and the fourth, a silver medal. The essays will be judged by a special commission and the results announced on the day of the centenary, May 2nd (14th), 1896.

Russian Mushrooms.

Mushrooms are found in immense quantities in the Russian forests. They form not only an important item in the diet of the peasant, but are also a considerable article of trade. There are some places, such as Vilkovishki (on the main line between Berlin and St. Petersburg), the inhabitants of which exist entirely by the sale of mushrooms. Kargopol again sends yearly to St. Petersburg as many as 5000 poods (a pood is thirty-six English pounds) of the fungi, representing in money value some thousands of pounds. M. Nadson recently read a very interesting lecture at the Botanical Gardens in St. Petersburg throwing much light upon the whole subject, particularly as to the differences between edible and poisonous forms of mushrooms. Fortunately, the poisonous forms are comparatively rare in Russia; but here, as elsewhere, there is no golden rule to distinguish them from the harmless. The lecturer mentioned an enormous number of varieties of both kinds; the most fatal seems to be the "pale *poganka*"; cases of poisoning from this form of toadstool have a mortality of 75 per cent. In Siberia the Samoyeds, Ostiaks, and Kamtchadales have long known the intoxicating properties of one form of mushroom—the *mukhomor*. Sometimes alone, sometimes mixed with the juice of a certain berry (the *golubika*), they make from it an

[1] THE LANCET, Aug. 10th, 1895.

Digitized by Google

infusion which has a stupefying effect similar to that of opium or hashish.

Diphtheria: Antitoxin Statistics.

The following figures are from the government of Podolia. They are published by Dr. Zabolotnui in a local journal and quoted in the *Meditzinskoé Obozriénié*. In 109 cases proved bacteriologically to be true diphtheria injections of anti-diphtheritic serum were employed. The number of deaths was 14; the percentage death-rate was, therefore, 12·8. Previously, under the older forms of treatment, the death-rate had been 48 per cent. Prophylactic injections were given to 228 healthy persons, stated to be members of families in which cases of diphtheria had occurred. None of these persons contracted the disease. Dr. Zabolotnui himself underwent the treatment for an attack of diphtheria and describes graphically the rapid subjective improvement after the first injection; the disappearance of headache and of the apathetic state into which he had fallen, with corresponding rise in spirits and improvement in all the specific symptoms. The temperature fell from 39·6° C. to normal after the second injection.

St. Petersburg, Aug. 19th (31st).

NEW YORK.

(FROM OUR OWN CORRESPONDENT.)

Protection of the Inmates of Hospitals against Fire.

AT the last session of the Legislature of the State of New York a law was passed which provides that all hospital buildings used for general hospital purposes, or asylums or hospitals for the insane, or any hospital buildings that are more than two storeys high shall have properly constructed iron stairways on the outside thereof, with suitable doorways leading thereto from each storey above the first for use in case of fire. It shall be the duty of the trustees, managers, owners, or proprietors of such hospitals or asylums to cause such stairways to be constructed and maintained. If the trustees or owners of any hospitals, except those owned and maintained by a city, a county, or the State, shall fail to provide such stairways before Oct. 1st, 1896, then the local authorities shall proceed to erect such stairways, and the cost thereof may be recovered by an action at law from the property of the said hospital. The district attorney of each county is charged with the execution of this statute, except in the case of hospitals erected by the State, city, or by a county. This law is to take effect on Oct. 1st, 1895.

Temperance v. Crime.

In the annual report of the State Board of Pardons of Ohio attention is called to the fact that the board has in most cases deemed it prudent to include in the recommendation for pardon a condition requiring abstinence from the use of intoxicating liquor. This is done in the belief that it will lessen the liability of the pardoned prisoner to again commit the crime. "It is a conspicuous fact," says the report, "that in nearly every case of crime against the person the offender was either under the influence of liquor or became involved in an affair by reason of being in a place where intoxicating liquor was sold."

A State Board of Health commended by the Legislature.

The State Board of Michigan, one of the oldest and most useful health organisations of this country, has recently been investigated with gratifying results. The committee concludes as follows: "Your committee find that the Michigan State Board of Health, as at present organised, is one of the most useful and worthy of the departments of our State government. Through it the people have received the unrequited and the unselfish labours of distinguished citizens of our State who stand pre-eminent among the sanitarians of the country. The board has attained a renown second to none among all similar organisations in the world. It has organised and developed a public health service in this State second to none in efficiency, and which has added to the health, life, happiness, and prosperity of our people. It has materially reduced sickness and deaths from several preventable causes, and it is a demonstrable fact that these labours have resulted in an actual money saving to the people of this State many fold more than their cost."

Obituary.

PROFESSOR DE SURY.

THE Swiss school has just lost one of its most distinguished representatives in Dr. Ernest de Sury, Extraordinary Professor of Legal Medicine in the University of Bâle.

Born of a good old Helvetian family at Soleure on April 30th, 1850, de Sury when still a boy removed with his parents to Bâle, where his education was thenceforward carried on. At the university he became a zealous and proficient student of medicine and graduated with great distinction in 1874. His first professional post was that of assistant physician in the lunatic asylum at St. Gall, which he held with much acceptance for four years, until, finding himself too isolated for scientific, especially clinical, observation, he returned to Bâle. There his exceptional ability, his pleasant address, and his high integrity rapidly drew round him an influential *clientèle*. He was particularly successful with that class of patients who have contracted the "invalid habit" till they seem almost to nurse their ailments and pride themselves on proving that their case at least is too difficult for medicine. It was here his alienist experience happily intervened, not a little aided by a geniality which disarmed querulousness. The same characteristic made him extremely popular among the poor, his skill, always at their service, being enhanced by a generosity so delicate that he never burdened its object with the sense of obligation.

His connexion with the University of Bâle dates from 1880, when he opened a "cours libre" in forensic medicine. His lectures were largely attended and numbered many "post-graduates" among their hearers. In recognition of his philanthropy and public spirit, especially in behalf of the poor, he received the freedom of the city of Bâle in 1883 and in 1887 was elected to the Grand Council of State by the constituents of the Spaten quarter. He was a member of not a few commissions, on which his judgment and experience, professional and lay, were of conspicuous service, particularly on the commission for making assurance against illness compulsory, and that for reserving the Sundays intact for the repose of the working man. In 1890 he was promoted by the University as Professor Extrordinary of Legal Medicine, and was in the zenith of his powers and his popularity when, on the 26th ult., he was suddenly cut down.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Ignacio Pirovano, formerly Professor of Clinical Surgery in Buenos Ayres.—Dr. Valentini, Surgeon-General in the Prussian Army, at the age of seventy-seven.—Dr. Slawczynski, one of the oldest and most respected members of the medical profession in Berlin.—Dr. Friedrich Miescher, formerly Professor of Physiology in Bâle, at Davos, after a long illness, at the age of fifty-one.—Dr. Pasquale Landi, Professor of Surgery and Operative Medicine in the University of Pisa, aged seventy-nine.—Dr. Texier, Professor of Internal Pathology in the Medical School of Algiers.—Dr. E. Góth, Extraordinary Professor of Midwifery and Gynæcology in the University of Clausenburg.—Dr. Francesco Bertè, Professor of Anatomy in Catania.—Dr. W. C. Jarvis, Professor of Laryngology in the University of New York.—Dr. Luigi Galassi, Professor of Special Medical Pathology in the University of Rome.

VACCINATION GRANT.—Mr. C. M. Leakey, L.S.A., of Caistor, has received for the second time a grant for successful vaccination as public vaccinator for district No. 2 of the Caistor Union.

THE following members of the medical profession have been selected for admission to the Order of the Hospital of St. John of Jerusalem in England, or enrolled as Honorary Associates of the order:—As Knights of Grace: Mr. Charles Edward Milnes Hey, M.R.C.S.; Sir William Overend Priestley, M.D., LL.D.; Deputy-Inspector-General Belgrave Ninnis, M.D., R.N. Enrolled as Honorary Associates: Mr. Reuter Emerich Roth, M.R.C.S., of Sydney, New South Wales; Mr. John Edward Squire, M.D.; and Mr. Alfred Croudson Tunstall, M.D.

Medical News.

APOTHECARIES' HALL.—The following candidates passed the Preliminary Examination in Arts on Sept. 6th and 7th:—

First Class.—None.

Second Class.—F. G. Cross, O. B. Gauntlett, F. S. S. George, C. J. Graham, G. W. Greene, J. W. Harrison, M. Mulrhead, D. S. Sandiland, and F. W. Smith.

The following passed in one or more subjects:—

N. Hodgetts, S. C. Jellicoe, A. B. Muscott, T. Richards, S. Rogers, and H. Tilbury.

FOREIGN UNIVERSITY INTELLIGENCE.—*Bâle:* Dr. R. Metzner of Freiberg has been appointed to the chair of Physiology in succession to Dr. Miescher, resigned. Dr. Fritz Egger has been recognised as *privat-docent* in Medicine.—*Barcelona:* Dr. Gil Saltor Lavali, Professor of Histology, Normal and Pathological, has been appointed to the chair of Surgical Pathology.—*Breslau:* Dr. A. Buchwald, *privat-docent* in Medicine, has been granted the honorary rank of Professor. Dr. Jacobi has been appointed Professor of Forensic Medicine.—*Bonn:* Dr. Finkler has been promoted to the Ordinary Professorship of Hygiene.—*Columbian University, Washington:* Dr. W. Reed has been appointed to the chair of Bacteriology and Pathology, and Dr. M. T. Phillips to that of Hygiene.—*Catania:* Dr. M. Guzzardi has been recognised as *privat-docent* in Surgical Pathology.—*Granada:* Dr. Rafael Mollá y Rodiguez of Havana has been appointed Professor of Clinical Surgery.—*Genoa:* Dr. Canalis has been promoted to the Ordinary Professorship of Hygiene.—*Greifswald:* Dr. Enderlen has been recognised as *privat-docent* in Surgery.—*Harvard University:* Dr. Harold C. Ernst has been appointed Professor of Bacteriology.—*Leipzig:* Dr. Eigenbrodt of Bonn has been recognised as *privat-docent* in Surgery.—*Naples:* Dr. Gennaro de Luca has been recognised as *privat-docent* in Medical Pathology, and Dr. C. Conca as *privat-docent* in Materia Medica and Pharmacology.—*New York (Policlinic):* Dr. Wilbur B. Marple has been appointed Professor of Ophthalmology, Dr. W. R. Pryor Professor of Gynæcology, and Dr. W. R. Townsend Professor of Orthopædic Surgery.—*Prague (German University):* Dr. Ewald Hering has been recognised as *privat-docent* in Experimental Pathology. *(Bohemian University):* Dr. O. Frankenberger has been appointed *docent* in Laryngology and Rhinology; Dr. J. V. Rohon has been appointed Extraordinary Professor of Histology.—*St. Petersburg (Military Medical Academy):* Drs. Petersen, Mochukovski, and Hitikin have been made Honorary Professors.—*Tomsk:* Dr. F. Krüger of Iurieff (Dorpat) has been appointed Extraordinary Professor of Medical Chemistry.—*Tübingen:* The names mentioned for the chair of Ophthalmology vacant by the death of Dr. Nagel are Drs. Berlin of Rostock, Uhtoff of Marburg, and Schleich of Stuttgart.—*Würzburg:* Dr. K. Rieger has been promoted to the ordinary Professorship of Psychiatry.—*Zürich:* Dr. H. von Wyss has been appointed Extraordinary Professor of Forensic Medicine.

THE DRUG, CHEMICAL, AND ALLIED TRADES EXHIBITION.—As announced in our issue of Aug. 16th, the Drug, Chemical, and Allied Trades Exhibition, was opened on the 10th inst. at the Agricultural Hall. Though the display, compared with some of the huge exhibitions held in the Agricultural Hall from time to time, was small it was not devoid of interest, and the freedom of space between the exhibits afforded an opportunity of comfortable inspection and a relief from the usual crowded state of exhibitions of this kind. Viewed as a first attempt, moreover, the attendance of a fairly large proportion of visitors, especially in the evening, must have proved a source of encouragement to the organisers. Drugs were well represented, as were also mineral waters, artificial and natural; while glass-blowing and improved methods of distilling, percolation, &c., and other processes incidental to the preparation of pharmaceutical substances, afforded subjects of peculiar interest to those closely connected with the drug industry and allied trades. This inaugural movement is, we think, one deserving of support, since, apart from its inevitable commercial aspects, it should possess a distinctly educational value inasmuch as it is calculated to spread a knowledge of the improvements and progress that are desirable in so important a branch of industrial affairs as pharmacy and manufacturing chemistry.

THE LATE MR. REESE OF YSTRADGYNLAIS.—The very sudden death of Mr. Reese, L.F.P.S. Glasg.—who was instantly killed by lightning while on his way to visit a patient—created such an amount of sympathy and kindly feeling, not only among the workmen to whom he acted as medical attendant, but also among the public at large, that a general desire has been expressed that funds should be collected for a memorial stone to be erected upon his grave and a testimonial in money to be presented to his widow. On Aug. 7th a public meeting was held, at which a committee was formed and officers appointed, whose names appear below, for the purpose of collecting funds, and they have every confidence that their appeal will receive a liberal response when sympathisers know that Mr. Reese had not insured his life and that his widow and eleven children, four of whom are quite young, have been left unprovided for. Chairman: Mr. John Rees, M.E., Seven Sisters, Neath. Hon. secretary: Mr. Thos. Watkins, Castle Bank, Ystradgynlais. The Rev. E. L. D. Glanley, Rector of Ystradgynlais, has kindly consented to act as treasurer.

VISIT OF THE SHAHZADA TO ST. THOMAS'S HOSPITAL.—The Shahzada, attended by Sir Michael Biddulph, Sir Adalbert Talbot, Sir Acquin Martin, Surgeon-Major Leahy, Colonel Mahomed Husan Khan, Colonel Mahomed Akram Khan, and other members of his suite, visited St. Thomas's Hospital on Aug. 31st. His Highness spent the whole afternoon in the wards of the hospital and in the medical school. He inquired as to the foundation of the hospital, the manner in which it was supported, and then personally inspected the whole working of the institution, visiting the wards, examining the surgical appliances, and asking for a demonstration of the whole method of carrying out antiseptic surgery in the operating theatre. The arrangements for heating, ventilation, cooking for the patients, the dispensing of medicines, and the recording of hospital cases were also studied by him with much interest. The Shahzada also visited the Nightingale School for Nurses; and he minutely inspected the whole arrangements for the teaching of students in the Medical School. The Pathological and Anatomical Museum especially attracted his interest, and he asked for information regarding medical education in this country and discussed what he saw with the members of his staff present. His Highness, besides warmly expressing his thanks for what had been shown him, was pleased to make a generous donation of £150 to the fund at present being raised to clear off the debt and completely open the hospital.

LITERARY INTELLIGENCE.—The works promised by Messrs. J. & A. Churchill to be ready for the winter session include "Mental Physiology, especially in its relation to Mental Disorders," by Dr. Hyslop, assistant physician, Bethlem Royal Hospital, and the third edition of Dr. Clowes' and Mr. Coleman's "Quantitative Chemical Analysis." The same firm also announce that they have the following works in preparation: "A Manual of Midwifery," by Dr. Lewers, obstetric physician to the London Hospital; "A Students' Text-book of Mental Diseases," by Dr. Percy Smith, resident physician and medical superintendent, Bethlem Royal Hospital; "A Handbook of Diseases of the Eye," by Mr. Jessop, ophthalmic surgeon to St. Bartholomew's Hospital; a fifth edition of Dr. Lloyd Roberts' "Practice of Midwifery"; a third edition of Mr. Jacobson's "Operations of Surgery"; and Professor Reynolds Green's second and concluding volume of his "Manual of Botany," treating of the classification and physiology of plants.—Messrs. Longmans will shortly publish "The Life of Sir Henry Halford, Bart., G.C.H., M.D., F.R.S., President of the Royal College of Physicians, Physician to George III., George IV., William IV., and to Her Majesty Queen Victoria," by William Munk, M.D., F.S.A., Fellow and late Vice-President of the Royal College of Physicians of London. Also "The Life and Letters of George John Romanes, M.A., LL.D., F.R.S." Written and edited by his wife. This life of the well-known naturalist, the friend and disciple of Darwin, includes correspondence between Mr. Romanes and Mr. Darwin; also many of Mr. Romanes' letters to scientific men and to private friends.—Her Royal Highness Princess Christian has accepted the dedication of a new novel, entitled "Perfect Womanhood," from the pen of Mr. Frederick James Gant, F.R.C.S. Eng. It will be published at the end of September by Messrs. Digby Long and Co.

Digitized by Google

LIFE-SAVING AND AMBULANCE WORK ON THE SOUTH COAST.—With its usual crop of bathing casualties the past summer, more, perhaps, than has been the case in any previous year, has been noticeable on the south coast for the long list of rescues and restoration to consciousness of the apparently drowned. At Brighton the police have been several times publicly complimented by the magistrates on their promptitude in the matter of first aid. Quite recently a soldier, brought from the sea in an absolutely unconscious condition, was practically resuscitated by the efforts of a constable. In reference to the fireworks fatality in Preston-park, on which occasion no less than a score of cases were treated at the Sussex County Hospital, it was stated at the inquest that but for the good use made by the police of their ambulance training the deaths must have been more numerous. Both in Brighton and Hove a large majority of the policemen have passed one or more of the St. John examinations. In the matter of rescue it has been especially gratifying to note the bravery of onlookers at an accident. At Portsmouth last week a yacht capsized, and at once two men swam to the rescue, one of whom, entangled in the sunken shrouds, had to be himself aided. Here no life was saved. At Worthing a young man fetched a bather from the bottom and induced respiration artificially afterwards by means of half an hour's hard work. At Eastbourne, Hastings, and on the rivers the same thing has been done more than once. The Royal Humane Society's awards have been made in many of these instances, and they have done much to keep before the public the undoubted value of life-saving and ambulance instruction.

Parliamentary Intelligence.

NOTES ON CURRENT TOPICS.

Close of the Session.

THE short session of the new Parliament, which opened on Aug. 12th, was brought to a close on Thursday, Sept. 5th, when the Queen's Proclamation was read in the House of Lords.

HOUSE OF COMMONS.

THURSDAY, AUG. 29TH.

Health of the Troops at Aldershot.

Mr. Brodrick, Under Secretary of State for War, replying to a question by Mr. Pierpoint, said that during the last six months there had been admitted to the hospitals at Aldershot 137 cases of diphtheria and 525 cases of sore-throat. In the latter the returns did not differentiate septic sore-throat. In the diphtheria cases the type had been that known as "benign," and they had readily yielded to the antitoxin treatment, only one death having resulted from this complaint. Although full investigation was made, in none of the cases could the origin of the disease be definitely traced. Some medical officers, however, were inclined to ascribe its prevalence and that of septic sore-throat to the recent necessary opening up of the old drains for the purpose of reconstruction. The question was engaging most careful attention.

The Government and the Unemployed.

Mr. Herbert Lewis addressed a question to the First Lord of the Treasury asking whether the Government intended to take any, and if so what, practical steps to obviate distress arising from want of employment during the coming winter. The reply to this question was made by Mr. Chaplin, President of the Local Government Board, who said that the Government fully appreciated the importance of the subject, and would watch very closely any increase of destitution due to want of employment, with every desire to render such assistance as circumstances admitted if and when the conditions during the coming winter foreshadowed by the hon. member should unhappily arise.

Insanity and the Use of Alcohol.

Mr. McKillop addressed a question on this subject to the Local Government Board, and Mr. Jesse Collings replied that he was afraid it would be impossible to obtain a return by the medical officers of asylums in the United Kingdom showing what percentage, if any, of the patients in their experience suffered from temporary or general madness arising from the presence of fusel oil, ether, methylated spirits, antimony, or other adulterant poison in spirits consumed by the people of the country; but he would consult the Commissioners in Lunacy to ascertain whether it were possible, and he would communicate with the hon. member. In the report of the Lunacy Commissioners for the present year the hon. member would find a return of the cases of insanity caused by intemperance generally. The proportions were 20 per cent. of males and 8 per cent. of females. The hon. member would find the exact figures in the report and other information bearing on the question of insanity and intemperance.

The Local Government Board in Ireland.

The vote for the salaries and expenses of the Local Government Board in Ireland gave rise to a long discussion at this sitting with regard to various matters connected with public health in Ireland.

Mr. Power called attention to the want of hospitals for the accommodation of persons who could afford to pay a little towards their maintenance.

Mr. Tully complained of the increase in the vote in respect of vaccine lymph, declaring it to be due to indiscriminate and wholesale revaccination carried on in some districts. He also called attention to night nursing in union hospitals and to the accommodation of pauper lunatics.

Mr. Farrell criticised at length the constitution of the Board.

Mr. Gerald Balfour, the new Chief Secretary for Ireland, replying to these and other speeches, claimed for the Local Government Board that it had not been remiss in dealing with special cases of distress in Ireland, and announced that he himself intended at a very early period to visit the poorer districts and see with his own eyes the exact state of things. He admitted that the treatment of the sick in workhouses left very much to be desired, and he assured the House that the Local Government Board were at the present time doing their utmost to induce guardians to improve the condition of things in their hospitals, and more especially the system of night nursing; but, as he had said before, it was not unwillingness but want of resources that prevented the guardians in poor unions from doing better things for the sick in their hospitals. There was a great deal to be said in favour of sending pauper lunatics to asylums instead of to workhouses, but he feared that at present there was not sufficient accommodation in the existing asylums to receive all the pauper lunatics.

Mr. Power, speaking as a Poor-law guardian in the Cork Union, said that he had seen something of asylums for pauper lunatics in Ireland, and he regarded these institutions as a public scandal. The medical officers were at work early and late and were most inadequately paid.

Mr. Arthur O'Connor invited the Chief Secretary to consider the treatment of paupers in England and compare it with what he found in Irish workhouses. Let him compare the dietary scales in English and Irish workhouses. Let him then consult any medical authority he chose upon what was necessary to keep a human being in normal health, and he would find in no English prisons or workhouses was such a dietary scale known as prevailed in Irish workhouses. According to all medical testimony the whole dietary scale in Irish workhouses was far inferior to that in English workhouses. For many years his efforts to induce different Irish Secretaries to deal with this question had failed, but he was bound to say that he had great hope that the present Chief Secretary would remedy the evil if he found that it really existed.

Mr. Gerald Balfour delivered another speech, in which he undertook to consider in a sympathetic manner the different points that had been put before him.

FRIDAY, AUG. 30TH.

Factory Laws on the Continent.

Sir Matthew White Ridley said, in reply to Mr. Drage, that his attention had been called to the report of the Chief Inspector of Factories for the year 1894, and the *précis* drawn up by one of Her Majesty's inspectors (Miss Anderson) of the regulations under the factory laws of France, as well as the general regulations with respect to sanitation, ventilation, and the restrictions placed on the employment of women and children in French industrial establishments. He had communicated with the Chief Inspector of Factories, who told him that he hoped to include in the next annual report a *précis* of the Austrian and German law on the same subjects.

The Marching Powers of the Army.

Mr. Brodrick said that the attention of the Secretary of State for War had been drawn to the statements as to the number of soldiers in the force now mobilised for the manœuvres in the New Forest who were unable to keep up with their regiments and had fallen out of the ranks on the line of march, and he had called for full reports on the subject from the general officer commanding. Until these reports were received no opinion could be expressed as to defects in marching or as to the causes of such defects. The Secretary of State was alive to the importance of good marching under service conditions, and the results of the manœuvres in this respect would be carefully considered by the military authorities.

MONDAY, SEPT. 2ND.

The Water-supply of London.

On the motion of Sir Albert Rollit a return was ordered showing as regards each water company supplying water in the metropolis—(*a*) the name of each metropolitan parish where the supply throughout the parish is a constant supply; (*b*) the name of each metropolitan parish where the supply is a constant supply only in part of the parish, and, in the case of each such parish, a description of the part of the parish where the supply is constant; (*c*) with respect to each parish at whose instance the constant supply was ordered or given; (*d*) the name of each metropolitan parish where the supply throughout the parish is intermittent; (*e*) the name of each metropolitan parish where the supply is intermittent only in part of the parish, and, in the case of each such parish, a description of the part of the parish where the supply is intermittent; and (*f*) with respect to each parish or part of a parish where the supply is intermittent the period during which water is supplied daily to the premises of consumers.

The Boots of the Army.

Mr. Brodrick, answering a question put by Mr. R. G. Webster, said that, owing to the difficulty of obtaining hand-sewn boots fully up to standard in sufficient quantities for the requirements of the army, it was decided some years ago to restrict the issue of hand-sewn infantry boots to regiments serving abroad. The machine-sewn boot issued at home was somewhat cheaper, but there was no reason to suppose it was less durable. It was, however, unquestionably stiff and heavy, and experiments were being made with the view of introducing a lighter and more flexible boot. The shape of the boot would also be considered.

Ventilation and Sanitation of the Houses of Parliament.

Mr. Akers Douglas, replying to a question by Mr. Weir, said that his attention had been directed to the subject of the ventilation and sanitation of the Houses of Parliament, and he would further consider it during the Recess. His examination of the question so far led him to regard with confidence the general system which was now in operation, and which was supported by the decisions and recommendations of the Select Committees which had so recently investigated the matter. He was not at all prepared to adopt the views of Mr. Keith, whose knowledge of the arrangements appeared to be imperfect. In some parts of the building there was, he thought, room for improvement in the ventilation, and these would be carefully looked into.

The Case of Dr. Herz.

Mr. Byron Reed asked the Under Secretary of State for Foreign Affairs whether the British and French Governments had come to an

Digitized by Google

agreement regarding the modification of the extradition laws between the two countries, so that for the future any person whose extradition was demanded might be examined at his residence without being arrested; and, if so, whether it might be understood that this applied to the case of Dr. Cornelius Herz.—Mr. Curzon replied that Her Majesty's Government had suggested to the French Government that a supplementary convention should be signed in order to give effect to the Extradition Act (1895), and had reason to hope that there would not be any difficulty in coming to an agreement. No convention had, however, yet been signed.

TUESDAY, SEPT. 3RD.

Provision for the Aged Poor.

Mr. Balfour, in reply to a question with regard to the form the proposed further inquiry into this subject will take, said that he could not make any final statement, but the inquiry would not be by a committee of this House, but would probably be departmental. If it was he trusted it might be at work before the next session of Parliament.

Post-mortem Examinations in Scotland.

Mr. Caldwell asked the Lord Advocate to explain why it was that in the case of William Agnew, shoemaker, Glasgow, who was tried for murder at Glasgow on the 29th ult. and acquitted, the Crown refused permission to medical men appointed by the prisoner to be present at the post-mortem examination of the deceased. This matter, he said, was causing very great interest in Glasgow. He did not believe that in any other country in the world a prisoner would have been refused the application to have two medical men present on the occasion of the post-mortem examination. It was a case of circumstantial evidence, and it was known that the most material link would be the post-mortem examination by the medical men. Accordingly the prisoner applied that two medical men, whose names were mentioned to the Procurator-Fiscal—men of eminence in Glasgow—should be present on his behalf, and the application was refused by the Crown authorities. The matter would obviously not stand reasoning, for undoubtedly a prisoner was entitled to bring forward medical evidence to rebut that of the prosecution, and it was essential for the defence that they should have all the material necessary to present their case.

The Lord Advocate replied that as soon as he began his duties he found that this matter was prominently brought before him, and he hoped it would content the hon. member if he answered him that his predecessor had only commenced an inquiry into the expediency of any modification of the practice in this matter. He had succeeded to that inquiry, and was prosecuting it as actively as he could. He said that without any pronouncement one way or the other as to the expediency of changing the practice, but no one knew better than the hon. member that it had been the practice of many successive Lord Advocates to hold to the principle that in conformation with the Scotch system of criminal inquiry—which he had yet to learn did not possess the confidence of the public—the Lord Advocate and the Crown officials had always held that it was within their discretion in each particular case to allow the presence of outside medical men. At the necropsy a prisoner could on application obtain an investigation for himself; but to allow outside medical men to be present at the post-mortem examination which was made on behalf of the Crown was a question which could not be decided offhand. He did not think the hon. member was correct in saying that the medical profession in Glasgow were unanimous on the subject. He had evidence, at all events, that certain members of the profession in Glasgow did not take that view. But he did not think it would be appropriate on this occasion and at this stage of the inquiry which was now going on to say anything further.

WEDNESDAY, SEPT. 4TH.

A Herbal Specific for Hydrophobia.

Mr. Farrell asked the Chief Secretary to the Lord Lieutenant of Ireland whether his attention had been called to the death from hydrophobia, at Hyde, of a young man named Haywam, who had been previously treated for that disease at the Paris Pasteur Institute. Whether he was aware that Philip McGovern, of Glan, county Cavan, claimed to possess a specific herbal remedy for the treatment of this disease, which had resulted in the cure of thousands of cases since the days of King Charles I. And whether, having regard to the necessity of doing something to cope with the increase of rabies, the Government would cause an inquiry to be made into the efficacy of this remedy, with a view to its adoption and use in some central hospital in Dublin or elsewhere.

Mr. Gerald Balfour replied that his attention had not been called to the unfortunate occurrence mentioned in the first paragraph of the question, nor was he aware of the remedy for hydrophobia for which Philip McGovern claimed so much efficacy. As regarded the last paragraph, he was afraid he must maintain the same attitude of caution and reserve which, to judge from the hon. member's question, had been adopted by Irish Governments ever since the days of Charles I.

BOOKS ETC. RECEIVED.

BAILLIÈRE, TINDALL, AND COX, King William-street, Strand, London.

Illustrations of Pathological Anatomy. By Professor Dr. A. Kast and T. Rumpel. English edition, revised and edited by M. A. Ruffer, M.D. Oxon. Parts 9, 10, 11, 12.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

PRINCIPALS' CLAIMS TO FEES PAID TO ASSISTANTS.

To the Editors of THE LANCET.

SIRS,—A is an out-door assistant and lives a hundred yards from his principal, B. At 10 P.M., two hours after A has left B's premises and is in retirement and in his dressing-gown, he hears a horse furiously gallop past his door, and knowing it has bolted hurriedly gets up and finds a horse at a standstill a few yards from his door, and a trap smashed all to bits. Learning there have been people thrown out, A hurries on as he is and sends a boy for his cap, thinking the occupants of the trap may be only a few yards from him, but has to go into the country half a mile. There he finds a woman, unknown to him, partly conscious, suffering from injuries to the head, and, receiving the help of another carriage, superintends her removal home and sees her in bed. He asks who is her medical attendant *en route*, and is told that her brother authorises him to call in his principal, B. B has not attended her for some years, but arrives, and B and A minister to her wants. A sees her next morning, but B visits her till her death, which takes place twenty-two hours after the accident from concussion. A gives evidence on citation, and receives the usual fee, which B appropriates, of which A feels aggrieved. A holds that as he went out, as any ordinary Christian would, to render assistance, irrespectively of anyone found injured being anyone's patient, he is entitled to the fee. B holds otherwise. Both B and A would be much gratified by having your opinion. I am, Sirs, yours faithfully,

Sept. 9th, 1895. JUS CIVILE.

*** The case is somewhat exceptional. A acted as "any ordinary Christian" *should*—but not, certainly, as all ordinary Christians *do*—act. And for doing so he has his reward. But that is not exactly in the fees paid by the coroner. These have to be disposed of on professional principles. In so far as he was acting medically he was acting for his principal. The patient's friends wished the principal to be sent for, and doubtless would have sent for him had A not acted with so much prompt humanity as he showed. The case is somewhat out of the ordinary run of cases and one of those in which the fees should be shared equally between the principal and the assistant.—ED. L.

A. and X.—Judging from the statement before us—of course only a one-sided statement—we should say that X has much reason to complain of A's conduct. Let us dismiss one or two questions. The fact that A has only one qualification does not in any way affect X's duty or rights. Again, the question of "covering" does not arise. That offence exists only when an unregistered person is protected by one on the Register. What redress, then, has X? His legal claim to damages is rendered doubtful from the fact that the agreement is only that between an ordinary assistant and his principal, presumably binding him not to practise. But the cards and the plate implying partnership remove the case from an ordinary one of assistant and principal, and give strong colour to X's claim to be regarded otherwise. We could not willingly recommend his setting up in opposition to A if the contract forbids such a course; but in the absence of any such stipulation, and supposing the statement before us to be a complete and unbiased version of the facts, and A to refuse all compensation, we should not think it unreasonable for him to threaten A with commencing practice, subject to a lawyer's approval of the course.

Medicus.—Our correspondent does not give sufficient particulars for us to form an opinion on the *legal* responsibility of the principal. Did the illness arise during the term of service? What were the terms of the engagement between the assistant and the principal? But whatever the legal aspects of the question, no right-minded principal would fail to see that an assistant contracting fever in his service had a great claim on his consideration.

A Poor but Observant Student has not enclosed his name. We do not answer anonymous questions.

Portion of Slate Pencil in the Ear.—Our correspondent is strongly urged to consult a medical man.

PAYMENT OF ASSISTANTS IN ILLNESS.

To the Editors of THE LANCET.

SIRS,—Will you kindly advise me as to what is the proper thing to do in the following case? My assistant takes scarlet fever immediately on returning from his holiday. I will allow he caught it from one of his patients. He has been away for six weeks, and never done a stroke of work during that time. Is he legally entitled to his full salary during this period? He is leaving me, and has written to say he will not return. I am, Sirs, yours faithfully,

Sept. 7th, 1895. B. SEATON COCKELL.

*** The question proposed seems to be one as to the effect of an agreement, and the answer would largely depend upon its terms. But if, as probably is the case, the agreement provides that the service can only be terminated by notice on either side, and contains no provision as to the suspension of salary in case of incapacity from illness, then it would probably be held that the assistant was entitled to payment of his salary throughout the period of illness; but if he takes advantage of his position to break his agreement by discharging himself without proper notice, he would probably be held to have waived his claim to salary accruing due after the date of his becoming incapacitated.—ED. L.

M.A., M.B.—We cannot give an absolutely definite answer on the information before us. A, we suppose, has a perfect right to seek election, as we take it the post is thrown open by advertisement, and we see nothing in the facts before us to enable us to assume that B, because he has been on the out-patient staff, has any absolute right to be transferred to the in-patient, though as a matter of courtesy he naturally would be. But the contention of A that B cannot hold the post of in-patient *physician* because he has previously been *surgeon*, or rather medical officer to the out-patients, cannot be supported.

Mr. T. C. Maguire.—We never prescribe. The class of people mentioned is to be avoided.

THE PREVENTION OF HYDROPHOBIA.

A CORRESPONDENT sends us the following suggestion:—"That a county where cases of hydrophobia have occurred recently be taken and the dog licence fee be increased to at least two guineas. Such dogs to wear a collar with a special Government registration tally. All other dogs within that county to be done away with, the police to receive remuneration for every dog captured. That all dogs imported into that county shall have a health certificate and undergo a period of quarantine lasting two months (incubation period of rabies being from three to five weeks as a rule). With such measures strictly carried out we should be able to judge in five years or so, and if a very marked diminution in the number of cases of hydrophobia and rabies should occur, then the plan might be adopted over the whole country. In this way all muzzling might be stopped, and there are a great many people who would rather pay their two guineas licence fee than be compelled to put a muzzle on their pet dog each time they take it out."

Forceps.—The claim would not be a strong one; therefore not one to take into court. The patient gave notice beforehand, releasing the practitioner from his engagement. We should not advise any further action.

Mr. J. W. Hill, Snowdrop, Victim, and *M.*—We never prescribe or recommend individual practitioners. Our correspondents should consult their own medical attendants.

Mr. Howard Slater.—The other derivation is usually given as "ad æquales," which certainly seems more plausible than the one our correspondent cites.

Insurance might apply to the Secretary of the Medical Sickness, Annuity, and Life Assurance Society, 33, Chancery-lane, W.C.

A SIMPLE METHOD BY WHICH AN INVALID CAN BE TRANSPORTED BY RAILWAY SO AS TO RECEIVE ABSOLUTELY NO JOLTING.

To the Editors of THE LANCET.

SIRS,—The following details of my method of railway transport for invalids may prove of service to readers of THE LANCET if space for its insertion can be afforded.

If an injury should be of such a nature (spinal, cranial, or other), or if an illness be of such a character (nervous, for example), and in such a situation, as to necessitate removal with absolutely no jolting, a hammock should be procured, having spreaders and stout indiarubber bands between the terminal strings of the netting itself and the particular bands by which the hammock is to be slung. Whether the patient be on the railway line, public road, or in bed, the hammock should be placed under him with as much care as possible. If in bed it can be slipped under the blankets without moving the patient to any extent. Should the place from which the patient is to be removed be some distance from the departure platform, then the patient and hammock under him can be placed on any ambulance conveyance, or on a padded door or shutter, rather than be carried any great distance in the hammock only. Having got the hammock under the patient, and having arrived at the station platform and procured the help of two or three porters, if these should be required, a car of any class is to be reserved. The patient is borne into the car, and the hammock is slung upon the *diagonally opposite* stays of the luggage racks on either side. The rope-ends of the hammock had better be two or three in number at each end than a single one for various reasons, but particularly that one can be hanked on to a neighbouring rack-stay to give a further security, as well as resistance to any lateral swaying there might possibly be. Through the diagonal position of the hammock *in situ* the other diagonal corners of the car are left for attendants or nurses, who can very easily prevent any lateral swaying that might possibly occur *en route* when the train starts or stops, though no one need touch the hammock if extra cords are attached to it, one on each side about its middle, and fastened to an opposite rack-stay.

By the above method a patient can be conveyed from Aberdeen to London with little more shaking than is experienced on a journey from a hospital bed to the operating-room, if it is properly carried out. The apparatus required is so simple and inexpensive that railway companies might have hammocks such as the one described at their principal termini in case of railway accidents, suicides on the line, or for the convenience and advantage of those who for any reason or purpose desire to be removed to their own home or to a hospital when these may be some considerable distance away.

If accident hammocks were provided at the principal railway stations they could be conveyed by return train long distances after being telegraphed for. Surgeons or others would be in a position to direct by telegraph that a car shall be reserved at a particular station, and that an accident hammock shall be provided and porters' help at hand for any train that he might look out in his Bradshaw. Short and simple instructions might be hung up where the hammocks were stored, so that porters should at once know the proper use of them if their assistance were necessary.

I am, Sirs, yours truly,

Sept. 9th, 1895. HAYDN BROWN, L.R.C.P., L.R.C.S. Edin.

COTTAGE HOSPITALS.

To the Editors of THE LANCET.

SIRS,—Can you, or any of your readers, give me an idea as to the probable cost of a cottage hospital, thoroughly equipped, to hold four beds, and also an approximate annual expenditure to keep such a hospital in a state of efficiency?

I am, Sirs, yours faithfully,

Ramsbottom, Sept. 10th, 1895. B. CRAWSHAW.

Justice.—The best course will be to refer the clerk to the Infectious Disease (Notification) Act, 1889, itself. Section 11 is as follows: "A payment made to any medical practitioner in pursuance of this Act shall not disqualify that practitioner for serving as a member of the council of any county or borough, or as member of a sanitary authority, or as guardian of a union, or in any municipal or parochial office."

J. W. S.—A comprehensive list of books to be read and consulted by candidates for the diploma of public health was formerly issued by the University of Cambridge, and a copy of this can probably be obtained on application to Dr. Anningson, Waltham Sal, Cambridge, or from the Cambridge University Press Warehouse, Ave Maria-lane, E.C.

M.D. will be obliged if any of our readers can inform him whether there is an opening for medical or dental practice in or near Johannesburg.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

During the week marked copies of the following newspapers have been received:—*Star (Guernsey), Herts Guardian, Yorkshire Post, Midland Weekly Herald, Mining Journal, Sanitary Record, Australasian Medical Gazette, Guy's Hospital Gazette, North Middlesex Weekly Standard, City Press, Harrogate Advertiser, Surrey Advertiser, Local Government Journal, Brixton Free Press, Bradford Observer, Australian Medical Gazette, Weekly Free Press and Aberdeen Herald, Leeds Mercury, Local Government Chronicle, Liverpool Daily Post, Hertfordshire Mercury, Morning, Bristol Mercury, Crewe Guardian, Western Press, Echo, Birmingham Mail, Nottingham Daily Express, Sheffield Independent, Newcastle Daily Journal, Leicester Post, Daily News, Southampton Times, Blackpool Herald, Wakefield and West Riding Herald, County Council Times, Aberdeen Journal, Batley Reporter, Folkestone Express, Dumfries Standard, Holborn Guardian, Bucks Advertiser, Lincolnshire Echo, Derby Daily Telegraph, Banffshire Advertiser, Clifton Chronicle, Bath Herald, Newcastle Daily Journal, Times of India, Architect, Pioneer Mail, Le Courrier de la Press, Builder, &c., &c.*

A Clinical Lecture
ON
HYDATIDS OF THE PLEURA AND OMENTUM.

Delivered at the Middlesex Hospital on Jan. 25th, 1895,

BY SIDNEY COUPLAND, M.D., F.R.C.P. LOND.,
PHYSICIAN TO THE HOSPITAL.

GENTLEMEN,—The recent concurrence in Hertford Ward of two unusual examples of hydatid disease suggested to me the subject of this lecture; but I had no sooner decided to speak of them than I felt serious misgivings as to whether such a topic would, after all, prove of much practical advantage to you. I adhered to my intention, however, when I came to consider that occasionally even the study of rare cases of disease may be turned to much profit, since it may enable us to put to the test the diagnostic criteria we are daily using. It is obvious that a rare case of localised thoracic or abdominal disease must exhibit in its history or its manifestations some departure from the ordinary course of better-known affections of the same part, even if it does not present any so-called pathognomonic signs; and although we may not be able, because we have never met with such a case before, to make an accurate diagnosis, yet we may have fixed in our minds the points in which it seems to depart from the common type. This is particularly well illustrated in the two cases I propose to speak of to-day. Both are rare cases; they are, I believe, the first of their kind which I myself have seen, and it is highly probable that you may pass your whole career without ever meeting one of them again. I cannot, therefore, describe them with any view of enabling you to be prepared to make a diagnosis should a similar experience happen to you, nor do I select them from the mere interest which everything that is novel necessarily has for us, but rather to test the value of certain physical signs which we are habitually seeking.

Amongst human parasitic diseases—a class that may be said now to include even the great groups of infective disorders—hydatids are responsible for a large mortality. Their distribution is spread more or less over the whole globe, but to a varying extent in different regions. In the British Islands hydatid disease is not a very common affection, whereas in Australia it is comparatively so common that if a practitioner there meets with an anomalous thoracic affection—such, for instance, as the one I shall presently relate—it may occur to him, although it might never to us, that it belongs to this class of hydatid disease. In Iceland it is even more common than in Australia, some early writers on the diseases of that country actually estimated that at least one-seventh of the population of Iceland suffer from this parasite, but that statement has been called into question, and on more critical examination the proportion has been very sensibly reduced. However, you will see from the table, which Mr. Pugh has written out—extracted mainly from figures given in Dr. Davies Thomas's work on Hydatid Disease—that even with material from the most authentic sources the proportions vary very much in all parts of the world. These figures do not represent the total amount of hydatid disease met with in the places indicated, they only represent those persons who came under treatment (in hospitals mostly) suffering from this disease. They do not include those who have never exhibited symptoms of suffering from the disease, but in whom post-mortem observation has shown that hydatids exist. The figures referring to Middlesex Hospital are based on our Registrar's records for the twenty-six years, from 1867 to 1893, and show that of 32,319 persons admitted into the medical wards during this period only forty-four were suffering from signs of hydatid disease. But this proportion does not accurately represent the average incidence of hydatids in this community, for it must be familiar to you that now and again there are to be seen in the post-mortem room the relics of hydatid cysts in subjects who exhibited no signs of such infection during life, or, as happened lately in a case in Hertford Ward, the patient, having been formerly treated and cured of hydatid disease, may die in hospital from some totally different affection. The case I allude to was that of a man who died from stricture of the œsophagus, the malignant nature of which was held to be confirmed by the fact that he also had a very palpable, firm tumour of the liver. He had, however, passed his early life in Australia, and had many years ago been "tapped" there for hydatids of the liver. As the event proved, the tumour was, in fact, the shrivelled, semi-calcified remains of a hydatid cyst, whilst the œsophageal stricture was lacking in any obvious cancerous characters. Bearing such cases in mind, it might be nearer the truth to nearly double the above figures if the actual hydatid rate were to be estimated. The remaining statistics, collated from the exhaustive work by the late Dr. Davies Thomas of Adelaide, tend to show that in London 1 per 1000 of the classes admitted into hospital are treated for hydatid disease; that in some places—e.g., Breslau and Vienna—the proportion is much less; that in other parts of the world, as in Australia, it varies from twice to six times that figure, whereas in the practice of one Iceland practitioner the proportion was as high as 28 per 1000. It would be possible, by a comparison of the hospital reports which are now habitually published in all large towns, to draw up a more extended list, but the table before you will suffice to show the relative prevalence of the disease in London and other parts.

*Table showing the Relative Proportion of Patients admitted into Hospital suffering from Hydatid Disease.**

Place.	Total number of patients in hospital.	Number of cases of hydatid disease.	Proportion of hydatid disease per 1000 of all patients.
Middlesex Hospital (medical wards, 1867-1893)	32,319	44	1·3
London Hospital (medical wards, 1876-1881)	13,297	24	1·7
St. Bartholomew's Hospital (medical and surgical wards, 1880-1884)	115,402	108	0·9
St. Thomas's Hospital (medical and surgical wards, 1871-1881)	34,559	44	1·2
St. George's Hospital (medical and surgical wards, 1865-1879)	45,599	22	0·5
Breslau	85,062	20	0·2
Vienna...	360,713	38	0·1
Iceland: Ofjord (by Finsen) ...	596	16	28·5
Australia—Victoria (8 hospitals)	134,104	835	6·2
,, New South Wales ...	35,760	103	2·8
,, Adelaide	38,671	175	4·5
New Zealand	40,271	54	1·3

* The figures for the Middlesex Hospital are from the Medical Registrar's annual reports. The rest are extracted from Dr. Davies Thomas's work on Hydatid Disease.

The diagnosis of hydatid cysts in various organs, and the gravity of the disease depends largely on its situation, as well as on the liability of the cyst to suppurate. I need not recapitulate at length what is known of the life-history of the echinococcus. In its adult form it is a small tapeworm (Tænia echinococcus) inhabiting the intestine of a dog, and its ova, shed from the proglottides, probably gain entrance into the human body through the alimentary canal. It is not difficult to conceive of the manner in which the liberated embryo from this tract finds its way into the liver or into other organs through the blood-channels—the two seats most commonly attacked being the liver and the lung. Dr. Thomas collected nearly 1900 cases of hydatid disease from various sources, and found that in about 60 per cent. the hydatid has its seat in the liver, and in about 12 per cent. in the lung, thus leaving a comparatively small percentage to be distributed among the other parts and organs of the body, amongst which are to be found examples in the cases I am now about to relate, the one belonging to the chest, the other to the abdomen.

CASE 1. *Hydatids of pleura simulating pyopneumothorax; paracentesis; drainage; recovery.*—The more interesting of the two cases is that of a lad fifteen years of age, who was admitted on Nov. 2nd, 1894, with a note from Dr. Travers-Smith of the Kilburn Dispensary, which he was attending, to the effect that he was suffering from pleural effusion and urgently required hospital treatment. It appears

Digitized by Google

that the boy had been attending at the dispensary since Oct. 15th. On his first attendance Dr. Smith noticed that there were unusual features about the case, and he was recommended to go to a neighbouring hospital. This advice was rejected for a time, and meanwhile the boy kept to his bed, but attended at the dispensary occasionally. The actual illness began rather acutely on Oct. 12th, when he was attacked with headache, pain in the side, and feverishness, with severe cough. It appears, however, from inquiry that he had been really ailing for some months prior to this, for since the preceding Christmas he had been complaining of a pain in his left side and had also frequently suffered from cough. His mother says he had always been delicate since he was five years of age, when he received a burn on the chest. So far as we could gather from both her and the boy, it did not seem that he had ever had any spitting of blood. Their statements to us do not, however, tally with those in Dr. Smith's notes, where "hæmoptysis" had been put down as a previous symptom. When admitted the lad was very thin and anæmic, suffering from a certain amount of fever, the temperature being nearly 101° F., and he complained of aching pain in the left side and of a troublesome cough, but was singularly free from any marked dyspnœa. On looking at his chest, which was covered by an enormous scar from the burn which he received when he was five years old, it was seen to be markedly bulged on the left side. In a cyrtometric tracing made at the time, taken just below the level of the nipple, the left side is seen to be bulged both in front and behind. Then the movements of the left side were much impaired, and on palpation vocal fremitus was rather excessive from the second rib to the nipple, but below that level it was abolished; on the right side movements and fremitus were normal. On percussion the pulmonary resonance was normal on the right side of the chest, save that on the level of the fourth rib, midway between the nipple and the sternum, there was an area of dulness, extending on each side obliquely downwards to merge in the hepatic area below. On the left side the percussion note was not fully resonant, being rather impaired beneath the clavicle, and more so under the second rib, whilst a markedly tympanitic note occurred in a somewhat quadrangular area, laterally from the sternum to the axilla, and reaching from the third rib above to the fifth below. Below that there was absolute dulness, which extended over the ribs to the costal arch, completely obliterating the area of gastric resonance, known as Traube's "semilunar space." The apex of the heart did not occupy its usual position. It was seen beating on the right side below the right nipple. On auscultation we heard sounds which required some consideration to explain. The right lung signs were practically normal—if anything, rather harsh and exaggerated. On the left side the breathing was low-pitched and rather blowing at the apex, distinctly amphoric in the third interspace and the upper part of the tympanitic area in the axilla, but suppressed below this. Posteriorly there was no marked difference, except absolute dulness over the whole of the left back and diminished fremitus, and diminished breathing sounds. Two sounds were absent which we expected to find present. Whenever you get a cavity containing air or gas, sound is transmitted readily, and if the air space is considerable there is reinforcement of the echo due to this cavity. The bell-sound elicited by striking together two coins on the wall of the sac and auscultating at a distance from them is a characteristic sign of a cavity containing air. We tried to elicit it here, but in no part could we get that characteristic ring or bell-sound. Another sign was unexpectedly absent: there was no succussion splash. Further, there could be felt a smooth rounded swelling projecting from beneath the left costal arch, which we inferred was the displaced spleen. The urine was normal and the abdominal organs were apparently natural. The diagnosis was somewhat difficult. We had to explain the presence of this tympanitic area in front, limited as it was, and its connexion with the dull area below. You may remember that the conclusion arrived at at the time was that we had to do with an anomalous case of empyema, possibly from ulceration of a small tuberculous focus in the lung with limited pneumothorax. The condition might thus be one of pyopneumothorax, limited anteriorly by pleuritic adhesions. But if this were the true explanation of the signs, it yet was most anomalous and unsatisfactory. In the first place this hardly explained the remarkable and extraordinary displacement of organs—the heart beating under the right nipple, the spleen diplaced downwards and forwards; and, secondly, this extreme displacement of organs and bulging of the chest by a pyopneumothorax so limited in its gaseous contents that although the patient was lying on his back we did not have, as might be expected, tympanitic resonance over the whole front, but confined to an area above the fifth rib. The diagnosis of empyema did not seem satisfactorily to explain this singular fact, but as we were satisfied that the fever was probably due to the presence of pus there was no undue delay in making an exploration by means of an aspirator, with the result that about twelve ounces of dark-greenish inodorous pus, together with a considerable amount of gas, were withdrawn. The result was simply to increase the area of tympanitic resonance in front of the chest, with no change in the position of organs or any effect on the fever, so that it was quite obvious that there ought to be a free opening made, and on Nov. 6th Mr. Pearce Gould operated. He made an incision over the seventh rib, in the posterior axilla, excised a portion of the rib, and opened the chest, when there escaped a considerable amount of flaky, greenish-yellowy pus mingled with bubbles of gas and shreds of material which looked like inspissated lymph and pus. There seemed to be rather a large amount of this material, which did not apparently differ from that yielded by other cases of empyema of some standing. The operation was very successful, and the fever abated. The temperature fell to 99° and 98°, and for weeks afterwards maintained a normal range. The heart soon swung back to its normal position, the area of dulness to the right of the sternum disappeared, and gradually the left side of the chest-wall became retracted. These and other facts were recorded by the clinical clerk, Mr. Gittings, from time to time; but I will not weary you with their full recapitulation. Suffice it to say that in all respects there was very great improvement, and even the left lung seemed to be regaining its function. But there was one direction in which no further progress was made. As weeks went by and the sinus still remained patent, yielding daily from an ounce to two ounces of purulent discharge, it was clear that there must be something behind keeping up suppuration, or that the drainage was not as thorough as it should be. The local condition was not cured in spite of general improvement, and I therefore asked Mr. Gould to explore the sinus, either with a view of enlarging the outlet or of determining the cause of the continued suppuration. The exploration was carried out on Jan. 15th, and the result was the removal of a large quantity of shreds of translucent membrane, which on examination were found to be indubitably portions of the wall of hydatid cysts. Under the microscope, as you can see from the specimens on the table, this membrane presented the lamination characteristic of hydatid. To be sure, no scolices were to be found, but they are not always present. The extraction of these membranes and their identification threw a flood of light upon the whole case, whilst there can be no doubt that their removal has materially enhanced the prospect of the lad's complete recovery. The extent of the shrinkage of the chest, which has been in progress since the first operation, and is no doubt still going on, is seen when the cyrtometric tracing taken the other day is compared with that taken on his admission. Owing to the curvature of the spine, the contraction of the lung, and the recession of the sternum the antero-posterior diameter is actually lessened. It will further be seen that the left side of the chest is comparatively shrunken anteriorly. On percussion a tympanitic note, obviously due to the underlying stomach, has replaced the area of dulness which previously extended to the costal margin. The area of cardiac dulness is now almost normal and the heart can be felt beating below the left nipple. The percussion note is somewhat impaired from the nipple to the second interspace, but thence to the clavicle the note is even fuller than that on the right side. It may therefore be inferred that the left lung, which had been too long compressed to fully re-expand, has done so to a certain extent. As the lung has not expanded below, the diaphragm has risen, and the thoracic wall has fallen to the extent shown by the cyrtometric tracing. I may add that the spleen can no longer be felt, and its area of dulness is obscured by the stomach note.

Looking back now upon the history of the case, with the added knowledge so recently acquired, it may be asked whether the somewhat anomalous signs originally observed may be considered characteristic of hydatid disease of the lung or pleura? There are no distinctive signs of these conditions. Pulmonary hydatids may in their course and signs simulate phthisis, for cough and hæmoptysis are their usual

Digitized by Google

concomitants, and at a later period signs of excavation may be yielded by a suppurating cyst communicating with the bronchi. Or the existence of so formidable an affection of the lung may be first revealed by the development of signs of pleurisy, or of pneumothorax from rupture of the cyst into the pleura; or, more obviously, by its rupture into the bronchi, with expectoration of the membrane and scolices. A very remarkable case of pulmonary hydatid was made the subject of a clinical lecture by Sir W. H. (then Dr.) Broadbent some years ago.[1] In this case the right lung was occupied by an enormous cavity formed by a suppurating hydatid, which during life had yielded signs simulating those of pneumothorax. The patient had complained of pain in the chest for two months, but her fatal illness, which commenced abruptly, with a sense of "something giving way" in the chest after unusual effort, lasted less than three weeks. I cannot forbear quoting the lecturer's closing remarks in his commentary on this case. He said: "Was a diagnosis possible? and could we have done more for the patient had an accurate diagnosis been made? I will answer the latter question first. Had I known exactly the state of things I should certainly have ordered a free opening to be made into the cavity, and I am sure that we should have then have given the poor girl a better chance of recovery. In reply to the first I would say that a diagnosis, though difficult, was no doubt possible. I say so because I think that perhaps you or I might make out a similar case, were such a one to come before us. In order, however, to interpret the complex signs and symptoms offered by disease we must be prepared by personal experience or by acquaintance with the recorded experience of others; and until this case came under my care I did not possess the knowledge that hydatid disease could so nearly simulate pneumothorax." *Mutatis mutandis*, these words may well apply to the case we are now considering. A point of some importance is to determine whether in our patient the hydatid had its primary seat in the lung, the pleural complication being due to its rupture into that sac. We cannot speak with certainty on this matter, for, with the exception of the somewhat equivocal symptom of hæmoptysis, the history of our patient would be consistent with the rarer, primarily pleural affection. The fact that there were signs of limited pneumothorax does not, I think, militate against this latter view, and must be attributed to decomposition of the purulent contents of the hydatid, whose rupture coincided with the onset of the acute attack. In any case we have, happily, now good reason to believe that the patient has been freed from his disease and is practically cured, although with a permanently carnified lung.

Before finally leaving this question of diagnosis I should like to point out that the great displacement of the heart and spleen, and the other physical signs, seem to prove that the fluid was confined within a tense sac. Similar signs would have been yielded by a subphrenic abscess, but we had ocular proof that in this case the disease was above the diaphragm. Yet amongst the causes of subphrenic abscess, the majority of which are due to perforation of the stomach or intestine, one must not forget that hydatids take a share either in the more common case of hepatic hydatid or in that of hydatid connected with the spleen. The course of events, as now interpreted, was therefore probably as follows. At some time or other the boy became infected with the echinococcus, but whether directly from the one small dog which lived in the house, or indirectly from the consumption of uncooked vegetables—particularly that popular and wholesome article, watercress—it is, of course, impossible to say. Indeed, it is very rarely possible to trace the origin of any case, although there is ground for the belief that the greater prevalence of hydatids in Iceland, and perhaps also in Australia, is not remotely connected with the like (comparative) preponderance of the domestic dog. Ordinarily introduced through the stomach, the hydatid may find its final resting-place in any part of the body. It has been suggested that the larger proportion of pulmonary hydatids in Australia may be owing to the inhalation of the ova scattered in the dust in that wind-swept continent, but the hypothesis is not needed, for, once taken into the stomach, the liberated embryo may wander anywhere. In this case we believe that they found entrance into the left pleura, and, growing, compressed the lung, but not materially impairing health until the rupture of one cyst, or the suppuration of the mother cyst, excited the pleurisy and concomitant phenomena. That the correct diagnosis was not made on the occasion of the first incision is an instructive feature of the case; but it was owing simply to the fact that the material then escaping had none of the characteristics of hydatid membrane. Nor can we say even now that there is no hydatid in any other organ, for experience shows that a multiple distribution of these parasites is not uncommon, and that this is more likely to be the case when a region so rarely attacked alone, as is the pleura, is in question. According to Dr. J. D. Thomas the liver is the seat of hydatids in about 57 per cent. of all cases, the lung in about 12 per cent., and the pleura alone in only 1 per cent. It is curious that, whereas in Australia the proportion of pulmonary hydatids is above the average—namely, 16 per cent.—in Iceland it is considerably below it—namely, 2·7 per cent. (Finsen). In this country certainly hydatids of the lung are rare. Of the 44 cases in the Middlesex Hospital from 1867 to 1893, inclusive, there was only one in which the lung was primarily involved—i.e., 2·2 per cent. But 3 were peritoneal and the rest hepatic. This proportion of peritoneal cases is above the average estimated by Dr. J. D. Thomas, being over 6 per cent., instead of 1·3 per cent., which he gives. It has been raised still more in our own statistics by the recent occurrence of two (perhaps three) cases of omental and peritoneal hydatid, to one of which I will now briefly refer.

CASE 2. *Multiple hydatids of omentum; laparotomy; removal; recovery.* — The patient, a man forty-two years of age, was sent into the hospital by Dr. Mortimer of Horley on account of a painful swelling in the abdomen. He was admitted on Nov. 23rd, 1894, and stated that in the previous August he first began to suffer from abdominal pain, at first very severe. The pain was referred to the right side of the abdomen, in the iliac region. A liniment and a purgative were prescribed for him, and he resumed his work after four days. He remained free from pain until about three weeks before his admission, when it recurred in the same region, and on examination the swelling was discovered. He was a ruddy, robust-looking man, apparently in excellent health, his digestion being good, the bowels regular, and his only trouble being that connected with the swelling, which caused a manifest prominence in the right hypochondrium and adjacent part of the epigastric and umbilical regions. The tumour was smooth, ovoidal in shape, extending to the left as far as the middle line of the abdomen, to the right for five and a half inches from that point, above (in the recumbent position) nearly to the costal margin, and below to the umbilical level. The tumour, which when the abdominal muscles were contracted was proved to lie behind them, was mobile. As he lay in bed it clearly descended with the diaphragm in inspiration, and it could be moved from side to side for quite two inches. It was not difficult to place one's hand deeply between the upper margin of the tumour and the liver, especially when the patient was in the sitting posture, whilst on percussion there was not only resonance between the tumour and the costal arch, but over the greater part of the swelling itself. On the right the flank was also resonant. Manipulation did not elicit any tenderness, the pain complained of being of a dragging, aching character, referred to the right loin, especially when he was lying on the left side. Moreover, the tumour was only mobile towards the left; it could not be pushed towards the right loin. Its character was that of a tense, elastic body, possibly cystic. Various opinions were expressed as to the probable nature of the cyst. On the whole there was most concordance as to its being of renal origin, particularly as in the usual position of the kidney on the right side there was much less resistance on palpation than there was on the left. The late Mr. Hulke, however, whilst not discarding this view, thought it more likely that it was connected with the omentum, and credit must be given to Mr. Lock, who was then house surgeon to Mr. Hulke, for advancing the opinion that the case was one of hydatid cyst of the omentum. It is obvious that if it were renal—and its situation and mobility certainly did not accord with a cyst of the kidney, which still remained in place—the organ must have been dislocated, perhaps a movable kidney. Only in this way could its appearance in front of the colon be accounted for. The patient was transferred to the care of Mr. Gould, who performed laparotomy on Dec. 12th. Before the abdomen was opened, and when the patient was fully anæsthetised, the cyst could be freely moved in every direction, and Mr. Gould therefore concluded that it was a

[1] THE LANCET, Oct. 26th, 1878.

Digitized by Google

omental hydatid. So, indeed, it proved, and it was readily detached from the surrounding omentum. The cyst was about the size of an ostrich's egg, its wall being translucent and its contents clear. In addition, there were found three smaller cysts (omental hydatids are always multiple), one as large as a Tangerine orange, the others quite small. The liver was free from any cyst. The recovery of the patient was uninterrupted, and he left the hospital on Jan. 16th, 1895. We may hope that he has been entirely relieved of his unpleasant parasite, although it would be rash to assert this yet; for, in a serous sac like the peritoneum, when once a hydatid has gained entrance it may become disseminated to remote parts, and perhaps some day fresh trouble may arise from the appearance of a similar cyst, say in the recto-vesical pouch. At any rate there is this comfort that we have no evidence of hydatid in connexion with any of the solid abdominal viscera.

ON PRESYSTOLIC APEX MURMUR WITHOUT MITRAL STENOSIS.[1]

BY ARTHUR G. PHEAR, M.D. CANTAB., M.R.C.P. LOND.

THE connexion of the mitral presystolic murmur with stenosis of the mitral orifice was first placed on a firm basis by Fauvel[2] in 1843, who gives an account of three cases in which the diagnosis thus made by the stethoscope was verified post mortem. He enters into the exact rhythm of the murmur with some care, describing it as a "bruit de râpe," commencing in the silence following the second sound and terminating at the instant the first sound is heard. Walshe[3] in 1851 was the first of British authors to draw attention to the murmur so significant of obstructive narrowing of the mitral orifice; he also was careful to define its rhythm with precision, describing it as post-diastolic or presystolic rather than exactly coincident with the diastole. Subsequently mitral constriction and its physical signs received special notice at the hands of Gairdner,[4] Hilton Fagge,[5] and others; and the view rapidly gained ground that not only did mitral constriction produce a presystolic apical murmur, but, further, that such a murmur was conclusive evidence of narrowing of the mitral orifice. For some years this sign was regarded as an almost infallible indication of organic mitral disease. Yet so early as 1862 two cases were published by Austin Flint[6] in which a mitral presystolic murmur had been heard during life, but in which the necropsies revealed no morbid change of the mitral orifices or valves. The same author described another case of similar nature in 1883,[7] and three years later in an article on "The Mitral Cardiac Murmurs"[8] he discussed the mechanism of the production of this anomalous murmur. Subsequently similar cases have been placed on record by Guitéras,[9] Osler,[10] Charlewood Turner,[11] Graham Steell,[12] Gairdner,[13] Maguire,[14] Lees,[15] and Sansom[16]—nineteen cases in all, in which the absence of mitral stenosis was ascertained by post-mortem examination. A feature common to sixteen of these was aortic regurgitation, and a close connexion has been held to exist between this condition and the presystolic murmur in question. More recently a number of cases has been collected by Theodore Fisher[17] in which presystolic or diastolic apical murmurs have been present in association, not with narrowing of the mitral orifice or with incompetence of the aortic valves, but with adherent pericardium. Two cases of like nature are recorded by Graham Steell.[18] In the Lumleian Lectures of 1894 the late Dr. Sturges has alluded to the frequency with which presystolic murmur is met with in children without the discovery of corresponding stenosis post mortem.

It is proposed in this paper to give an account of two further cases[19] of presystolic apex murmur without mitral constriction. In both the aortic valves were competent; in one the pericardium was adherent and in the other case this structure was healthy.

CASE 1.—A girl aged ten years and a half was admitted to University College Hospital complaining of severe headache and vomiting, probably of uræmic origin; these had been present in some degree for a year; no account could be obtained of any previous acute attack of nephritis; there was no history of scarlet fever or of rheumatic fever. The child was very anæmic, but not dropsical. From twenty to thirty ounces of pale urine were passed daily, containing a small quantity of albumin. The fundus of each eye showed extensive degenerative changes with hæmorrhages. It is noteworthy that the radial arteries even at this early age showed evidence of degeneration, the walls being thick and fibroid; the pulse was regular, but could be compressed without difficulty. The condition of the heart at the time of admission was as follows. The præcordial region was not bulged. An impulse was visible in the fourth and fifth left interspaces, its maximum point lying in the fifth interspace just to the outer side of the nipple line; the impulse was localised and of heaving character. The stethoscope revealed over this area a loud, low-pitched systolic murmur, obscuring the first sound and conducted outwards to the axilla; on this occasion no other apical murmur was heard: at the base a systolic murmur of hæmic origin was audible over the second left interspace; the second sound here was accentuated, but not reduplicated. A fortnight later a diastolic murmur had presented itself at the apex: this new murmur was of rough quality and of low pitch; its rhythm was not constant; at one time it immediately followed the second sound, and at another there was a short but definite interval between the second sound and the commencement of the murmur; occasionally it was presystolic, running up to and becoming merged in the systolic murmur; on one occasion it occupied the mid part of diastole, being separated by an interval from the second sound on the one hand and the systolic murmur on the other. During the child's residence in the hospital her condition gradually deteriorated. There was a steady diminution in the output of urine; obstinate vomiting set in, muscular twitchings appeared, and death ultimately ensued from uræmia.

Necropsy.—The heart was found to be hypertrophied, particularly the left ventricle, the walls of which were in places more than half an inch thick; the muscle was firm in consistence. The chordæ tendineæ attached to the mitral valve were both thickened and shortened; the curtains of the mitral valve showed no further deviation from the normal than a slight degree of thickening; the mitral orifice admitted two fingers; this in a child aged ten years cannot be regarded as a condition of narrowing. The aortic valves were healthy except for a little thickening at the attached margin of one of the cusps; they were perfectly competent. The tricuspid and pulmonary valves and orifices were normal, and the pericardium was healthy. The kidneys were very small and contracted, weighing together less than three ounces.

CASE 2.—A male patient was under observation on several occasions during a period of five years. His first illness of importance in the present connexion occurred at the age of thirteen in 1888, when he was admitted to University College Hospital for chorea. The attack was not a severe one and rapidly gave way to treatment. The heart at this time was normal. He had not long recovered from chorea when he fell a victim to rheumatic fever, of which there had previously been abundant manifestations among his family, although the boy himself hitherto had escaped. This attack kept him from work for more than two months and was almost immediately followed by a second outbreak of chorea. About a

Digitized by Google

year later he again came under observation, this time suffering from acute pericarditis. In addition to the signs of a moderate degree of pericardial effusion there was to be heard a to-and-fro friction sound, systolic and diastolic, of rough but superficial quality, the maximum intensity being at the base. There was also a rough systolic murmur at the apex, conducted to the axilla and round to the back, and presumably endocardial. Three weeks later he was convalescent. Friction was no longer audible; but the systolic apical murmur remained, and note also was taken of a systolic basic murmur, probably of hæmic nature. Some eighteen months after this he was again admitted to the hospital on account of severe pain in the region of the heart and shortness of breath. There was no fever, and the pulse—from 90 to 100 per minute—was regular and of fair tension. A diffuse undulatory impulse extended over the left intercostal spaces from the second to the sixth inclusive. In the fourth and higher spaces the chest wall could be seen to recede at the moment of systole. In addition to the systolic murmur, which presented the same features as before, there was to be heard at the apex and in its immediate vicinity a harsh presystolic murmur. The temporary benefit derived from treatment soon disappeared on the boy's departure from the hospital, and the progress of the case during the ensuing year and a half, though irregular, was on the whole one of progressive deterioration. On the occasion of his admission to the hospital for the last time in October, 1892, he was wasted and was suffering from bronchitis with slight hæmoptysis. Though the lungs were thus hampered there was no evidence of tricuspid regurgitation, the veins of the neck were not visibly pulsating, and dropsy had not made its appearance. The præcordial region was bulged. An impulse was visible over a wider area even than before, extending now for nearly an inch to the left of the left nipple line; the impulse was of heaving character and preceded by a *thrill*, of *presystolic rhythm*, confined to the region of the apex. No presystolic murmur, however, was to be heard on this occasion; that of systolic rhythm was as conspicuous as before. The disappearance of the presystolic murmur was only temporary; three weeks later it was again to be heard, and in addition a third murmur had made its appearance in the mitral region, of low pitch, rather rough quality, and occupying the early part of diastole. Occasionally the presystolic murmur was absent. The thrill also was variable, being at one time presystolic, at another time early diastolic, and occasionally absent. At the base the pulmonary second sound was accentuated; no murmur was audible. In the course of time signs of cardiac failure developed; the pulse became frequent and irregular; pulsation appeared at the epigastrium and in the veins of the neck; the legs became tense with dropsical fluid, which collected also in the peritoneal cavity; and the liver became enlarged and pulsatile and a slight degree of jaundice developed. The more urgent symptoms were, however, relieved by means of digitalis and by draining the fluid from the legs by incisions; the subcutaneous dropsy was in this manner reduced, and even for a time disappeared. The abdominal cavity remained, however, as tense as ever with ascitic fluid, which accumulated again and again in spite of repeated tappings; this was taken to indicate that permanent cirrhotic changes had developed in the liver—a conclusion which was justified subsequently. Throughout the later stages of the disease a distressing symptom was pain in the region of the heart, occurring in paroxysms especially at night-time. The termination of the case was abrupt, being due to syncope.

Necropsy.—There were extensive and firm adhesions of the pericardium, both to the heart and to the chest wall. Both sides of the heart were dilated, the left to a greater extent than the right; the left ventricle was hypertrophied. The mitral valve and the chordæ tendineæ were thickened and the curtains of the valve slightly adherent; the mitral orifice admitted three fingers with ease. The aortic valves were slightly thickened, but perfectly competent; a row of minute granular vegetations was present on the ventricular aspect of each cusp near its free border. The liver was small, its surface being roughened and capsule thickened; its substance was very tough, and there was evidently a marked excess of connective tissue.

It appears that a murmur may be audible over the mitral area which, though independent of mitral narrowing, resembles the murmur of that condition in that it may occupy the beginning, middle, or end of the diastolic period; it may be of early diastolic, mid-diastolic, or presystolic rhythm. The frequency with which aortic regurgitation is associated with this murmur renders it necessary to consider how far, in dealing with a murmur of mitral locality and of early diastolic rhythm, it is possible to exclude conduction from the aortic orifice as its cause. The difficulty is always great and is often insuperable. The presence or absence of a diastolic basal murmur affords but little help; if present it does no more than indicate that the aortic valves are incompetent; if absent, still the aortic valves may be diseased, producing a murmur audible only at the apex. The area of audibility of the aortic regurgitant murmur probably depends more on the amount[20] and strength of the reflux current than on any other factor; for it to be heard at the apex, not only must the valvular defect be considerable, but for the production of forcible recoil the initial strength of the heart beat must be great; so the heart is found hypertrophied and the pulse of characteristic "water-hammer" quality. As a rule, the apical diastolic murmur of mitral origin is accompanied by neither cardiac hypertrophy nor water-hammer pulse. The quality of the murmur, though of subsidiary importance, yet may afford help. That produced by aortic regurgitation is of high pitch, "whiffing" in quality, and becomes raised in pitch (or rather the lower-pitched of the elements of sound constituting the murmur become lost) as the stethoscope is shifted from the base in the direction of the ensiform cartilage or apex; the mitral diastolic murmur is of low pitch and comparatively harsh quality.

The murmur of presystolic rhythm stands on a different footing; this cannot anyhow be mistaken for a conducted aortic regurgitant murmur, contrasting as it does not only in quality but in rhythm. Various explanations have been offered of the manner of its production. It was suggested by Keyt[21] that the murmur, though preceding the first sound, was truly of systolic rhythm and generated at the aortic orifice. Charlewood Turner also supposes that the murmur, though apparently presystolic, in reality occupies the commencement of systole; he maintains that it is due to dilatation of the ventricle, a condition which allows regurgitation of blood through the mitral orifice, the reflux, however, being transient and confined to the commencement of systole, since, he argues, when a certain amount of contraction has been accomplished, the mitral curtains, previously unable to meet, become competent to close the orifice. This explanation depends on the view, first enunciated by Ormerod,[22] and later supported by Barclay[23] and Dickinson,[24] that all the so-called presystolic murmurs are in reality not presystolic at all, but systolic in rhythm, and are due to mitral regurgitation. Among many difficulties in the way of accepting this theory attention may be drawn to three: 1. The murmur commonly designated as presystolic is in many cases not of short duration, but prolonged, occupying, in fact, the greater part of the diastole, commencing soon after the second sound, and gradually increasing in loudness and roughness up to the first sound or systolic murmur. 2. If the so-called presystolic murmur is due to regurgitation, why should it be present in some cases of regurgitation and not in all? It is at the commencement of systole that the blood will regurgitate, if at all; and it is at the commencement of systole that the murmur should be of most constant occurrence. 3. A murmur produced from beginning to end by regurgitation should be conducted similarly throughout its length. This condition is not fulfilled by the so-called double mitral murmur; the early part of this, usually described as presystolic, is heard over a limited area, being conducted in most instances to a short distance only from its point of greatest intensity, although at this point it is loud and rough; the murmur commonly recognised as systolic is conducted well and in a characteristic direction. Maguire believes the murmur in question to be closely related to aortic regurgitation. He propounds an ingenious theory, which is based on the anatomical relations of the anterior flap of the mitral valve. This lies in close proximity, not only to the mitral, but also to the aortic, orifice. He suggests that this flap, hanging between two converging currents, both flowing into the ventricle, the one from the aorta and the other from the auricle, is thus caused to vibrate, the vibrations being

[20] The late Dr. Hilton Fagge in his article on Valvular Disease in Reynolds's System of Medicine (vol. iv., p. 645) has expressed his belief that the murmur of aortic regurgitation is propagated in the direction of the apex when the regurgitant stream is large, and that hence it is of particularly unfavourable prognosis.

audible (as in the case of other mitral murmurs) at the apex. If the aortic regurgitant stream is copious, he says, there is produced an early diastolic murmur audible at the apex; in other cases the murmur is not produced until the auriculo-ventricular current is reinforced by the auricular contraction, which causes a vibration of the mitral flap of presystolic rhythm. An objection may be raised to this theory on the ground that the two currents are not both in action at the time when the presystolic murmur occurs; the aortic regurgitant flow has practically come to a standstill at the moment when the auricle contracts; under these conditions it seems hardly more probable that the auriculo-ventricular current should cause the mitral flap to vibrate than in normal circumstances. Again, given the simultaneous flow of the two currents, would not the valve hang passive between the two, supported on each side, rather than be thrown into vibration? If the valve were taut, and the current passing in the opposite direction so as to impinge on its free edge, doubtless vibrations would be set up, and a murmur, probably of musical quality, produced. The theory originally advocated by Flint presupposes as the immediate cause of the murmur what may be termed a "functional" narrowing of the aperture through which the blood passes from auricle to ventricle. He points out that in cases of aortic regurgitation the left ventricle rapidly fills with blood; the rapid inflow of blood, he suggests, floats the mitral valves away from the ventricular walls, so that they may actually be brought into coaptation before the commencement of the auricular contraction. With the auricular systole the valves, approximated as described, are thrown into vibration. An essential part of this, as of the theory propounded by Maguire, is aortic valvular disease, permitting regurgitation of blood. On either theory, then, the mitral presystolic murmur, though deprived of its former precise significance as a sign of diseased mitral valve, yet retains value as evidence of cardiac valvular defect. There have been described, however, by Osler, Graham Steell, Theodore Fisher, and in a previous part of this paper cases of presystolic murmur independent, not only of mitral stenosis, but of aortic regurgitation. Theodore Fisher draws attention to the frequent occurrence of adherent pericardium among these cases; he suggests that damage to the nerve-supply of the heart muscle may result from the antecedent pericarditis; hence loss of muscular tone and a condition favouring vibration of the muscular wall—vibration which may actually be set up by the blood propelled into the ventricle from a dilated and hypertrophied auricle.

Although so much attention has been directed to the presystolic apex murmur as occurring without mitral stenosis, the manner of production of this murmur remains obscure; the subject is, therefore, one worthy of further study. The size of the mitral orifice may be lessened by contraction of the fibrous ring to which the valves are attached, or by structural disease of the mitral valve, the segments of which may become thickened, shortened, and adherent, thereby leaving a much narrowed opening—it may be only a slit—for the passage of the blood. It seems possible also that the aperture between the curtains of the valve may become narrowed so as to obstruct the blood flow, independently of such gross organic changes, in a manner to be described. It is generally recognised that one function of the musculi papillares is, by their contraction, to draw together the flaps of the mitral valve and so aid in the closure of the mitral orifice. These structures (the papillary muscles) are disposed in the left ventricle in two groups, the one situated anteriorly and to the left, and the other posteriorly and to the right; from the former chordæ tendineæ pass to be attached to the free edge and ventricular surface of the anterior portions of both flaps of the mitral valve, the posterior parts of the valve being similarly connected by chordæ tendineæ with the posterior set of musculi papillares. The effect of this arrangement may be illustrated by a quotation from Foster's Physiology:[23] "From the disposition of the flaps of the valve and their relation to the papillary muscle, the chordæ tendineæ of a papillary muscle being attached to the edges of and spreading over the surfaces of two adjacent flaps, we may infer that when the papillary muscles contract, taking their share in the whole ventricular systole, they on the one hand bring at least the edges, if not part of the surfaces, of adjacent flaps into apposition, and on the other hand tend to pull down the whole of the valve, more or less in the form of a narrow funnel, into the cavity of the ventricle"—a condition of things almost identical, it will be noticed, with one of the varieties of mitral stenosis—valve edges in apposition, and the whole valve projecting in the form of a funnel into the cavity of the ventricle. By contraction of the papillary muscles, then, the valves are not only rendered tense, but are pulled downwards in such a way that their edges are brought into proximity, if not into apposition, and the mitral orifice, if not actually closed, is converted into a mere slit. Similar tension may be brought to bear on the valves by conditions other than contraction of the papillary muscles. Chordæ tendineæ are not infrequently seen in the post-mortem room presenting a thickened and contracted appearance. This is met with as one of the results of chronic endocarditis, accompanying more or less well-marked valvular disease. The condition is also seen, apart from any gross lesion of the mitral valve, under circumstances of strain such as is produced by the cardiac hypertrophy of Bright's disease or of aortic valvular disease. In such cases the mitral valves may present a normal appearance, or by slight thickening may show evidence of the strain to which they have been subjected; but the condition is not necessarily associated with the slightest degree of organic mitral stenosis. With shortened and thickened chordæ tendineæ the mitral valves are held permanently in the position which in the normal heart they are made to occupy rhythmically by the contraction of the musculi papillares; this practically amounts to a narrowing of the aperture through which the blood has to pass, and, given a fair auricular contraction, will be attended during life by a presystolic murmur, although post mortem it may be found possible to introduce as many fingers through the mitral orifice as in the normal heart. The first of the cases described above is an example of presystolic murmur without mitral stenosis proper, but with contracted chordæ tendineæ. Apart from the morbid change in the latter a similar condition of valvular tension may result from increase of the distance between the point of their origin and the line of insertion of the mitral valves. In the event of dilatation of the ventricular cavity the distance between any two points on the walls of the ventricle is increased. As the cavity gradually expands the two sets of musculi papillares from which the chordæ tendineæ spring are displaced away from the ring to which the mitral valve is attached, and at the same time become separated from each other. The downward displacement tends to put the valve on the stretch lengthways, and to draw the flaps together; the effect of the lateral movement is to produce tension along the line of the free edges of the valves. In this way the curve which is formed by the margin of each flap is straightened, and the aperture included by the flaps is elongated and narrowed. The manner of modification of the mitral orifice by displacement of the musculi papillares may be studied in the normal heart by detaching these structures from the heart wall and making slight traction with them in a downward and outward direction, away from the mitral orifice. It is submitted, therefore, that either of these two conditions—shortening of the chordæ tendineæ, or dilatation of the left ventricle—may produce a narrowing of the aperture through which the blood passes in its course from auricle to ventricle. A second factor, however, is necessary for the production of a presystolic murmur; this is the occurrence of an auricular contraction sufficiently forcible to generate a fluid vein. It is probably owing to failure in this respect that presystolic murmur is not a more common accompaniment of ventricular dilatation. The latter condition is frequently associated with dilated auricle; and dilatation of the auricle, unless combined with well-marked hypertrophy, means feeble auricular contraction — too feeble to provide the force requisite for the production of a murmur.

In conclusion I venture to suggest that many of the cases recorded of presystolic murmur without mitral stenosis, but with aortic regurgitation, may have been due to one or both of the conditions to which attention has been drawn above. In aortic insufficiency there is commonly some degree of ventricular dilatation; commonly, too, the chordæ tendineæ are thickened and retracted. Similarly, adherent pericardium is a condition of rarity apart from enlargement of the heart, the enlargement consisting of combined hypertrophy and dilatation in varying proportions. This may serve to explain the fact that, of the cases on record of presystolic murmur apart from narrowing of the mitral orifice, aortic incompetence has been present in so large a proportion, while in so many of the remainder adherent pericardium has been found.

The following is an abstract of previously recorded cases of presystolic apex murmur without mitral stenosis. The references will be found among the footnotes already given.

A.—Cases in which Aortic Regurgitation was present.

CASE 1.[6]—A male aged fifty-six in whom the impulse was strong, the apex beat being in the nipple line in the seventh left space. At the apex there was a presystolic "blubbering" murmur, and at the base a soft diastolic murmur conducted down the sternum. Post mortem the weight of the heart was 16 oz. There was hypertrophy of the left ventricle. There were a few vegetations on the mitral valve, but otherwise it was healthy. The aortic segments were sound, but insufficient from enlarged orifice.

CASE 2.[7]—Presystolic blubbering apex murmur; aortic direct and regurgitant murmurs. Post mortem the heart weighed 17½ oz. There was hypertrophy of the left ventricle; the mitral valve was healthy; the aortic valves were contracted and insufficient.

CASE 3.[8]—Presystolic and systolic apex murmurs; double aortic murmur. Post mortem the heart weighed 17½ oz.; the mitral valve was normal; the aortic valves were thick and contracted.

CASE 4.[11]—A male aged thirty-three. The impulse was diffused; the apex beat was in the nipple line, two inches below the nipple. There was an occasional presystolic thrill; a presystolic apex murmur occurred with every other beat, alternating with systolic murmur; there was a diastolic murmur after every beat, and a double basic murmur. Post mortem the heart weighed 20½ oz.; the mitral valves were much thickened, but competent, the girth of orifice being 4·79 in. The aortic valves were very incompetent and shallow.

CASE 5.[11]—A female aged thirty-two, with rheumatic history. There was a systolic apex murmur, at first by itself and later followed by soft diastolic murmur, almost continuous with the systolic, which commenced with presystolic character. Post mortem there was recent pericardial lymph; the heart weighed 20 oz.; both ventricles were enlarged; the mitral valves were thickened and incompetent, and the aortic valves were apparently incompetent.

CASE 6.[9]—There was a low-pitched, rumbling, presystolic murmur over the fourth, fifth, and sixth left interspaces, and also a double aortic murmur. Post mortem the heart weighed 21½ oz.; the mitral orifice admitted three fingers; the valve was opaque, slightly thickened, not adherent, and competent; the aortic valves were short and thickened.

CASE 7.[10]—A diastolic thrill was present in this case, and a loud, rough, presystolic apex murmur. Post mortem the mitral valve was normal, but the aortic yalves were extremely incompetent.

CASE 8.[13]—A male aged twenty-four. At the apex there was a brief, rather indefinite, auriculo-systolic murmur; later it was rather more decidedly auriculo-systolic. Aortic regurgitation was not entertained. Post mortem the heart weighed 16 oz.; there was a half-inch perforation in the right aortic valve. (The mitral valve was not mentioned, being presumably healthy.)

CASE 9.[14]—A male aged forty, with rheumatic history. The apex beat was one inch and a half outside the nipple line in the sixth space. A faint systolic apex murmur was audible, there being later a rather blowing presystolic murmur, limited to an area within and above the apex beat; still later this murmur disappeared. At the base systolic and diastolic murmurs were heard. Post mortem the weight of the heart was 22 oz. All the cavities were dilated. The mitral orifice admitted three fingers, the anterior flap of the valve being slightly thickened, and the ventricular aspect roughened; the chordæ tendineæ were neither thick nor short. The aortic valves were incompetent, thick, and shrunken.

CASE 10.[14]—A male aged fifty-five. The apex beat was without the nipple line, in the fifth space. In the fourth right space there was a diastolic murmur, conducted to the ensiform cartilage. Just below the left nipple there was a short, blowing, presystolic murmur; this became rougher and less localised, and later disappeared. Post mortem the heart weighed 25½ oz.; all the cavities were dilated; the chordæ tendineæ were healthy. The mitral orifice admitted three fingers; the valves were healthy, except for an atheromatous patch. The aortic valves were incompetent and much shrunken. An aneurysm of the left coronary artery bulged into the left auricle, but was free from the mitral orifice and the cusps of the mitral valve.

CASE 11.[15]—A male aged twenty-one, with a history of chorea followed by rheumatic fever. Presystolic and systolic murmurs were heard at the apex; later the presystolic murmur occupied a large part of the diastole; still later it disappeared; afterwards it reappeared, and the systolic murmur vanished. There was a double aortic murmur. Post mortem the pericardium was found to be completely adherent. The heart was much enlarged, especially the left ventricle. The mitral orifice admitted three fingers, the valve being thickened, and there was some recent endocarditis. The aortic valves were thick; fresh vegetations with ulcerations were present.

CASE 12.[15]—A male aged thirty. The apex beat was displaced considerably downwards and outwards. There were apex murmurs, at times being systolic and diastolic, and at other times presystolic and systolic. At the base a loud, rough systolic murmur was heard; a short diastolic murmur was localised in the second right space. Post mortem the heart weighed 27½ oz. The mitral orifice admitted three fingers; the valve was normal. The aortic valves were fused into a calcareous mass; an opening was left of the size of a cedar pencil, which would have directed the stream towards the mitral valve.

CASE 13.[13]—A male aged thirty-one. The impulse was between the fifth and sixth spaces two inches without the nipple line. There were a presystolic rumbling apex murmur and systolic and diastolic basal murmurs. Post mortem the weight of the heart was 35 oz. All the cavities were dilated; the chordæ tendineæ were normal. The mitral orifice admitted five fingers; the valve was normal. The aortic valves were slightly thickened and incompetent.

CASE 14.[15]—A male aged forty-five. The impulse was feeble. There was a local presystolic apex murmur of cantering character, and a systolic murmur to the left of this. At the base there was a loud systolic murmur, and a soft diastolic with maximum at the fourth left space. Post mortem the weight of the heart was 19 oz. The mitral orifice admitted four fingers; the anterior flap and the chordæ tendineæ were thick, but not shrunken; the posterior flap was slightly thickened. The aortic valves were much diseased and quite incompetent.

CASE 15.[16]—A male aged thirty. A well-marked presystolic thrill was present. There was a murmur over most part of diastole at apex, (?) ceasing for a very brief period before the first sound; also simulated reduplication of second sound. Post mortem there was no stenosis whatever of the mitral valves. The aortic valves were incompetent.

CASE 16.[26]—A male aged thirty-two. There was an apex beat in the nipple line in the fifth space. There was a presystolic thrill. At the apex there was a presystolic "rolling" murmur localised to the area of impulse; between this and the sternum there was a systolic murmur. At the base there was a diastolic murmur to the left of the sternum; behind the sternum there was a loud half-squeaking, half-musical murmur. Post mortem the pericardium was found to be healthy. The weight of the heart was 22½ oz. The left ventricle was hypertrophied. The mitral orifice measured 4 in.; the valve was healthy. The aortic valves were slightly thickened, the right posterior cusp was retroverted, and there was thickening of the endocardium over the septum where the regurgitant stream had impinged.

CASE 17.[26]—A male aged forty-five. The apex beat was in the fifth space three inches without the nipple line. There were a presystolic thrill and a harsh presystolic apex murmur. There was also a to-and-fro basal murmur. Post mortem the mitral orifice measured 4½ in.; the valve was normal. The aortic valves were not diseased, but incompetent from dilatation of the aorta. There was a thickened patch on the septum.

B.—Cases in which the Pericardium was entirely or partially Adherent.

CASE 18.[16]—A female aged nineteen. There was a history of rheumatic fever. There were a diastolic thrill, systolic and diastolic apical murmurs, with doubled second sound. There was also a systolic aortic murmur. The pulmonary second sound was accentuated. Post mortem the pericardium was found to be generally adherent. There was dilatation of all the cavities. The chordæ tendineæ were hard and short. The mitral orifice admitted four fingers, the valve was thickened, and there were vegetations on the auricular surface. The aortic valves were competent.

CASE 19.[18]—A male aged twenty-three. There was a

[26] Theodore Fisher: THE LANCET, March 9th, 1895.

Digitized by Google

diastolic thrill. At the apex there were a systolic murmur, doubled second sound, and a short diastolic murmur. At the base there were a systolic murmur and reduplicated second sound. Post mortem the pericardial cavity was found to be obliterated. The weight of the heart was 22 oz. There was great dilatation of the mitral orifice; the valve was thickened and indurated. The aortic valves were slightly thickened, but apparently competent.

CASE 20.[27]—A female aged twelve. At the apex there were a loud systolic murmur and a rumbling diastolic sound. Post mortem the pericardium was found to be adherent. The weight of the heart was 23 oz. There were hypertrophy and dilatation. The mitral orifice was dilated and the valve slightly thickened. The aortic valves were competent.

CASE 21.[27]—A male aged ten. There was a thrill (? rhythm). At the apex there was a systolic murmur, and after it a sound, probably a diastolic bruit. Post mortem the pericardium was found to be adherent. The weight of the heart was 10 oz. There were hypertrophy and dilatation. The aortic and mitral valves were healthy, except for bead-like granulations.

CASE 22.[27]—A male aged thirteen. At the apex there were a systolic and rumbling presystolic murmur. Post mortem the pericardium was found to be adherent. The heart weighed 22 oz. There were hypertrophy and dilatation. The mitral orifice was dilated. The valves were healthy.

CASE 23.[27]—A male aged twelve. There was a systolic thrill. At the apex was a systolic murmur, and later a diastolic murmur. Post mortem the pericardium was found to be adherent. The heart weighed 13 oz. There were hypertrophy and dilatation. The mitral orifice was enlarged. The valves were normal.

CASE 24.[27]—A female aged eleven. There were a systolic thrill and systolic and diastolic apical murmurs. Post mortem the pericardium was found to be adherent. The weight of the heart was 17 oz. There were hypertrophy and dilatation. The mitral orifice was dilated and the valves were thickened. The aortic valves were normal.

CASE 25.[27]—A male aged thirteen. At the apex was a systolic murmur, preceded by a rumble. Post mortem universal pericardial adhesions were found. The heart was greatly enlarged. The mitral orifice admitted five fingers.

CASE 26.[28]—A female aged eleven. There were a presystolic apical thrill, systolic apex murmur, and also a rumbling long diastolic murmur. Post mortem the pericardium was found to be universally adherent. The weight of the heart was 17 oz. The mitral orifice measured 4 in.; the valve was thickened. There were small granulations on the mitral and aortic valves.

CASE 27.[28]—A female aged seventeen. There was an apex thrill, now presystolic, now systolic. There were apical systolic and diastolic murmurs. Post mortem the pericardium was found to be adherent over the front of the left ventricle. There was great dilatation. The mitral orifice measured from 3¾ to 4 in.; the valve was thickened. The aortic valves were healthy.

CASE 28.[28]—A male aged fourteen. There were a systolic apical thrill and mitral systolic and mid-diastolic murmurs; at another time there was a localised presystolic murmur. Post mortem general adhesion of the pericardium was found. The heart weighed 21½ oz. The mitral orifice measured 4¾ in.; the valves were thick, but not shrunken. The aortic valves were slightly thickened, but not contracted.

CASE 29.[28]—A male aged nine. There were a mitral diastolic thrill, mitral systolic murmur, and a diastolic "rumbling" sound; there was no presystolic murmur. Post mortem universal pericardial adhesions were found. The heart weighed 10 oz. There were bead-like granulations on the valves, otherwise they were healthy.

CASE 30.[28]—A male aged nine. There were a systolic apex murmur and a short "roaring" diastolic sound. Post mortem the pericardium was found to be universally adherent. The weight of the heart was 10¼ oz. The mitral orifice measured 4½ in.; the valves were thick, but slightly shrunken, and fringed with small granulations. The aortic valves were healthy.

CASE 31.[28]—A male aged ten. There were a harsh systolic apex murmur and a long, rumbling, diastolic murmur heard over a wide area. Post mortem the pericardium was found to be universally adherent. The heart weighed 9 oz. The mitral orifice was capacious. There were recent vegetations on the valves.

CASE 32.[28]—A male aged thirteen. There were a systolic apex murmur and a rumbling presystolic murmur localised to the area of impulse. Post mortem universal adhesions of the pericardium were found. The weight of the heart was 22 oz. The mitral orifice took three fingers easily; the valves were healthy.

CASE 33.[28]—A male aged twelve. There was a systolic apex murmur. At different times a rumbling sound followed the second sound, and there were mid-diastolic and presystolic murmurs at the apex. Post mortem the pericardium was found to be universally adherent. The heart weighed 13½ oz. The mitral orifice was enlarged; the valves were scarcely thickened. The aortic valves were normal.

CASE 34.[28]—A female aged thirteen. There were presystolic and systolic apex murmurs. Post mortem the pericardium was found to be universally adherent. The weight of the heart was 10½ oz. There was no stenosis of the mitral orifice, but slight thickening and shrinking of the valves. There was a fringe of small granulations. The aortic valves were normal.

CASE 35.[28]—A female aged fourteen with systolic apical murmur, rumbling diastolic sound, and double squeaky pericardial rub. Post mortem recent adhesions of the pericardium to the front of both ventricles were found. The weight of the heart was 13¼ oz. The left auricle was dilated and hypertrophied. The mitral orifice took three fingers; the valves were thickened. Small granulations were present on the mitral and aortic valves.

CASE 36.[29]—A male aged eighteen with a history of chorea and afterwards of rheumatic fever. The patient had a mitral systolic murmur, and later a variable diastolic murmur, now early diastolic, now presystolic, and at times absent; it was associated with a thrill. Post mortem the pericardium was adherent to the heart and chest wall. There was dilatation of both sides of the heart, especially of the left. The mitral orifice admitted three fingers; the valve was slightly thickened. The chordæ tendineæ were thickened, but not shortened. The aortic valves were competent; on them were small vegetations.

C.—Cases in which there was neither Aortic Regurgitation nor Pericardial Adhesions.

CASE 37.[11]—A male aged thirty-six in whom the apex beat was 2 in. on the outer side of the nipple line. At the apex there were systolic and long diastolic murmurs; with stronger beats there was a rough presystolic murmur, followed by a flapping first sound, but no systolic murmur. At the base there were an indistinct systolic and a diastolic murmur. Post mortem both ventricles were dilated and hypertrophied. The mitral orifice took three fingers; the valves were competent; the margins were thick and rough. The aortic valves were thickened, but showed no patency.

CASE 38.[11]—A female aged thirty-five with a history of rheumatism. There were a systolic thrill and a systolic apex murmur; later a presystolic murmur appeared, and the systolic disappeared. Post mortem the heart was somewhat enlarged symmetrically. The mitral orifice measured 4½ in. The mitral and aortic valves were normal.

CASE 39.[10]—A child with a presystolic mitral murmur. The heart was pushed upwards by an enormous spleen. Post mortem the mitral valve and orifice were found to be normal.

CASE 40.[27]—A male aged eight. There were a systolic thrill and a systolic apex murmur, and in addition a low-pitched systolic and diastolic rumble. Post mortem the weight of the heart was 10 oz. The mitral orifice measured 3¾ in.; the valves were thick and contracted. The aortic valves were thick, but competent.

CASE 41.[28]—A male aged forty-six with a presystolic apex bruit. Post mortem the heart weighed 21 oz. The mitral orifice took three fingers; the valve was thickened. The kidneys were healthy.

CASE 42.[28]—A male aged eight with a systolic thrill. At the apex a hard, harsh, blowing systolic murmur was heard, and also a long rumbling sound, systolic and diastolic. Post mortem the weight of the heart was 10 oz. The mitral orifice measured 3¾ in.; the valve was thickened and somewhat shrunken. The aortic valves were thick, but not shrunken. The left auricle was dilated and hypertrophied.

CASE 43.[26]—A male aged forty-seven in whom a presystolic apex murmur was audible. Post mortem the mitral orifice

Digitized by Google

admitted four fingers. The aortic valves were adherent, but considered competent.

CASE 44.[36]—A female aged twenty. There were a presystolic thrill and presystolic and systolic apex murmurs; later a diastolic murmur replaced the presystolic. Post mortem the weight of the heart was 18 oz. The mitral orifice measured 3¼ in. The aortic valves were healthy. There were hypertrophy of the right ventricle and atheroma of the pulmonary artery.

CASE 45.[36]—A child aged eight. At the apex there were systolic and long, loud, diastolic murmurs. Post mortem the mitral orifice measured fully 3 in.; there were a few small granulations on the auricular surface of the valve.

CASE 46.[36]—A female aged eleven. There was an apical systolic murmur, and later a diastolic in addition, its place in the diastole varying, being now early diastolic, now mid-diastolic, and now presystolic. Post mortem hypertrophy of the left ventricle was found. The mitral orifice admitted two fingers; the valve was slightly thickened. The chordæ tendineæ were short and thickened. The aortic valves were normal. The kidneys were small and granular.

In 17 of these 46 cases the aortic valves were incompetent; in 20 the pericardium was adherent. In 12 cases presystolic or diastolic thrill was present; this cannot, therefore, be so certain a sign of mitral stenosis as has been supposed. The condition of the chordæ tendineæ is mentioned in seven cases only; in three of these they are recorded as healthy; in two they were thickened, but not short; and in two they were found to be shortened.

Gower-street, W.C.

NOTES ON A RECENT DEATH FROM LIGHTNING-STROKE AT SHOEBURYNESS, ESSEX.

By DAVID T. KEY, M.R.C.S. ENG., L.S.A.,
SURGEON-CAPTAIN VOLUNTEER MEDICAL STAFF.

DURING the recent meeting of the National Artillery Association at Shoeburyness, where I was doing duty as camp-surgeon, the following fatality occurred. On Tuesday, Aug. 6th, 1895, at 6.50 P.M., a man, whilst walking with a female companion along the footpath leading from South Shoebury to Shoeburyness railway-station, was struck by lightning and killed instantly. He was a London cab-driver, single, aged thirty, had been in the army, and was an army reserve man at the time of his death. The footpath is about six feet in width, having on one side a shallow ditch and a row of tall old elm trees, and on the other an iron railing about five feet high, the rails forming a row of pointed spikes six inches long above a horizontal bar. The tree nearest to the deceased was the last of the row. It was to the man's left hand, and the woman was between him and the railings. They were walking. There had been no rain for about three-quarters of an hour. Deceased was perfectly dry. I saw him within four minutes of his death. He had fallen on his face diagonally across the path, with his head towards the tree. His face was livid and suffused with blood. His eyes were closed; yellow mucus was exuding. He was quite dead, so I had him placed on a small ladder and removed at once, as there were still frequent flashes of lightning, a possible source of danger to onlookers. There was probably a rise of temperature, for I observed the body was very warm to the touch, and there was a very powerful smell of burnt hair and flesh. His companion was thrown against the railings, but did not fall. She was able to answer my questions, but was very pale. She said she felt heat on the left side of her face. Her left ear was filled with débris of hair. On examining the body at 8.30 A.M. next morning, in conjunction with Surgeon-Colonel Coats, A.M.S., garrison surgeon, the body was found to be well nourished, muscular, and well developed. Rigor mortis was well marked. On examining the head the point of probable entrance of the electric fluid was found to be at the vertex, almost central; slightly to the left of the central line showed an oval excavation in the hair about one inch. No wound was apparent. The hair was all singed short over the left side of the head. The left eyebrow, eyelashes, and left side of the moustache were practically gone. Fluid was escaping from the left ear. On tracing the burns on the left cheek and under the left lower jaw several large ones were found on the left thorax and sternum; thence centrally over the abdomen. The hair of the pubes was all singed short; the scrotum was swollen and livid; thence along the inner side of the right thigh and calf over the internal malleolus, the point of exit of fluid being at the inner and central point of the right heel. The burns were of various sizes and interrupted, the largest being that on the sternum, about one inch and a half in diameter. The surface of the burns was dried. The epidermis was entirely destroyed and gone. On examining the clothing, the hat was found to be in small shreds, but the coat and waistcoat were very slightly damaged. A blue woollen jersey was not much damaged. The shirt (grey flannel) was split in the same direction as the burns, and a merino undervest next the skin was split in the line of the burns two-thirds from above downwards—the edges of this crumbled when handled, but were not charred black. There was a hole through the watch pocket. The trousers were split into long vertical ribbons in both legs, but more especially along the line of burns. The right pocket was blown to shreds (there had been about 14s. silver money in this, which was picked up at the time of removing the body). The drawers were very much torn. The boots were of the front lace-up pattern, the soles and heels of which were entire, but some brass nails had started in the sole of the right boot. Half of the inner uppers of each boot was entirely gone; also the metal eyelet holes. The right boot was blown off the foot entirely at the time of the accident. The collar and cuffs were in shreds. The necktie (a bow) was split in two in the middle. The tree showed a spiral interrupted track of the lightning, the bark being broken off. The lightning apparently left the tree about ten feet from the ground, and four days later I observed just below this point one small thin twig (only) about two feet long, the leaves on which had withered. This would correspond to a point about eighteen inches above the man's head. The following articles were found on the deceased:—Money—besides the silver—in left-hand breast coat pocket, inside: Thirty-seven sovereigns and twenty-eight half-sovereigns in a common leather jaw-opening purse which had a metal rim and closed by two small knobs. The coins (nearly all) were wrapped in separate pieces of thin paper and the purse tied up in a handkerchief. In the waistcoat pocket, on the right side, a silver match-box containing two unignited wax matches and silver Geneva watch (no chain) were found. There was also a gold ring on one of the fingers. A pocket knife was also found. With regard to the condition of the coins, two half sovereigns were slightly fused and adhering together; one sovereign was partially fused on one side as though a splash of metal had been thrown on it. Many more of the gold coins showed traces of fusion of the milling of the edges only; several of the silver coins also showed similar fusion of the edges. The watch (open-faced) had a hole a quarter of an inch in diameter through the outer case by the hinge, and on opening this there was a splash of metal on the rim of the dome, and another on the bow. The watch had stopped at 6.55, but could be wound up. The steel hair-spring would not recoil, as probably it had lost its temper. The watch glass was broken. The ring and knife showed nothing. The metal rim of the purse had a small point of fusion on one side—inside—and the purse also had a hole through one side of the leather.

It would be interesting to know whether the base of the skull was fractured, as fluid was seen issuing from the left ear and not from the right one; whether from the apparent direction of the electric fluid in the line of the left pneumogastric nerve this would sooner affect the heart's stoppage; and, also, whether the deceased received the whole of the discharge or whether any passed over the woman's head to the pointed railings. There can be but little doubt that the gold attracted the lightning. Had deceased not been immediately under the tree his head would probably not have been struck first, but the gold would have received the discharge direct. The path of the lightning also should be noted—from the largest burn on the *left* chest (close to the heart's apex) through the watch pocket to the gold, thence to the *right* trousers pocket, touching the watch on its way, and giving a slight radiation towards the match-box. A violent explosive force was expended in the right trousers pocket so as to blow it to pieces and throw the silver coins towards

[36] Duckin: The Diseases of Childhood, p. 415.

Digitized by Google

and under the railings, where most of them were picked up at the time of removing the body. The next greatest force was expended in the right boot so as to blow away the adjacent inner sides of both boots. I gave evidence at the inquest, but the coroner would not give me leave to make a post-mortem examination, which no doubt would have added still more to what has been to me a case of great interest.

Reading, Berks.

NOTES OF TWO CASES OF ENUCLEATION OF THYROID CYST.[1]

BY W. H. BROWN, F.R.C.S. IRELL.,
SURGEON TO THE GENERAL INFIRMARY AT LEEDS.

THE treatment of cystic goitre has hitherto been of a disappointing character, and the methods mentioned in the various text-books have always, so far as I have seen, been attended with much febrile disturbance and great personal discomfort, not to mention the uncertainty of success and the very tedious progress towards convalescence. In the two cases which follow I adopted the plan first carried out, I think, by Dr. Vachell of Cardiff in 1885. The cases are so alike in many points that I do not propose to make anything like a detailed separate report. I can supply any particulars that may be asked for as being important. Both tumours occurred in young unmarried women aged respectively eighteen and twenty-five years. The growths had been noticed between three or four years. No inconvenience had arisen until within a few months of my seeing them. There was no evidence of any general nervous disturbance or blood change. The reason they sought advice was the same in both cases—i. e., an occasional difficulty in swallowing and attacks of dyspnœa, the latter becoming gradually more severe and increasing in frequency. Upon examination, the tumours were firm and elastic, painless, and occupying the position of the left lobe of the thyroid gland. The tumours were almost the size of a large orange, fluctuation could not be made out, and the circumference of the neck was fifteen inches over the most prominent part of the swelling. Under ether I made an incision three inches and a half long over the most prominent part of the swelling down on to the capsule of the cyst. All bleeding caused by the incision was next stopped by pressure forceps, then with the finger and a blunt director the cyst was stripped from its attachments, steady sponge pressure following up this process; after that, the cyst having been freed on both sides, I opened it and allowed the fluid contents (about four ounces) to escape. This permitted of more room in the wound cavity and enabled me to complete the detachment of the posterior surface of the cyst wall with greater freedom of manipulation. After the removal of the tumour the cavity was packed with sponges for a few minutes; this effectually did away with any tendency to oozing. To give some idea of the depth of the wound, I may mention that it required six fair-sized sponges to fill it. After the washing out with carbolic water the wound was closed in the ordinary manner, and a large rubber drainage tube was inserted at the lower angle. This was removed after twenty-four hours. In both cases union by first intention was obtained, and the after-treatment does not need mention save perhaps that in the first week the patients were kept constantly upon the back, their heads being firmly fixed between two large sandbags. In neither case was there any important rise of temperature. Both patients are now well.

Until quite recently I had looked upon thyroid enlargement of this character as being somewhat beyond satisfactory operative treatment. The list of remedies given in the text-books does not mention one that in my opinion can be compared with the plan I have just described, and which, by the way, is not spoken of in any surgical work to which I have had access, save in Heath's Dictionary, where Dr. Felix Semon suggests that enucleation *might possibly* be undertaken, but does not advocate it, and by Mr. Jacobson, who advocates antiseptic excision, but quotes a case which is not very encouraging. In his recent work on tumours Mr. Bland Sutton states that all cystic growths of the thyroid gland have their origin in adenomata and that they can readily be shelled out from their bed, whether cystic or solid: and lately I have had the opportunity of verifying the statement by enucleating an adenoma of the thyroid gland in a girl of fifteen, the operation being perfectly straightforward. This case is also doing well. So far as I have seen, the operation itself is not difficult; once the tumour has been fairly exposed hæmorrhage ceases to be troublesome. In stripping the cyst wall I used the finger and blunt director, and thus avoided lacerating the gland tissue; unless this be done hæmorrhage of an embarrassing nature must occur. The originator of this operation worked through a small incision, opening the cyst at once and dragging it out of the wound afterwards. I prefer a freer opening so as to be in a position to command a good view of the wound cavity. In the second case the wound was fully five inches in depth, going down behind the sternum; and bleeding from such a distance would be most difficult to combat through a small incision. I need hardly point out that in this operation every detail of cleanliness must be most carefully observed, as carefully indeed as within the peritoneum; for nothing could more readily end in disaster than septic infection of the thyroid gland, and given that infection, septicæmia of an almost certainly fatal character would follow. Now that the distinction between the general enlargement of the thyroid gland and a growth in that gland, whether cystic or solid, has been made clear, and the fact that the latter can be dealt with by a safe operation having been demonstrated again and again, the operation of enucleation will probably soon obtain recognition in the text-books and become more general. It may often be impossible to say whether a given swelling is solid or cystic—in such cases exploratory puncture will help towards a diagnosis; but even if that should prove negative as to the presence of fluid, if the tumour appear to be in the thyroid gland and not of it, then operation can be entertained, as evidence Mr. Sutton's statement and my later case. Let it not be supposed that this operation applies to all cases of thyroid enlargement. Selection must be made or disaster will follow, and odium will be cast upon what is to my mind a very valuable addition to the surgery of the thyroid gland. Since writing the above I have had brought to my notice Mr. Charters Symonds' paper read before the Clinical Society in which he advocates operative treatment very much on the same lines, and quotes many successful cases.

MELANCHOLIA, WITH SPECIAL REFERENCE TO ITS CHARACTERISTICS IN CUMBERLAND AND WESTMORLAND.[1]

BY W. F. FARQUHARSON, M.B., C.M. EDIN.,
ASSISTANT MEDICAL SUPERINTENDENT, CUMBERLAND AND WESTMORLAND COUNTIES ASYLUM, CARLISLE.

THE subject of melancholia has many features of interest both for the general practitioner and for the asylum physician, and it is one that should give rise to much useful discussion. The family physician has the advantage of seeing the case at its onset, of studying the causes that have led to it, of watching its gradual development and growing intensity, of adopting measures for combating the attack in its earlier and more curable stages, and finally in severe cases it often devolves upon him to decide as to the necessity for asylum treatment; and his knowledge of the family history and surroundings of the patient must prove of great service to him in giving his prognosis and in formulating his treatment. The asylum physician, on the other hand, only sees the more severe cases, and those as a rule only after they have undergone treatment for a longer or shorter time at home; nor has he in many cases the same opportunities for ascertaining all the particulars as to the personal and family history of his patients.

Nature of melancholia.—Melancholia is characterised by the presence of mental depression out of proportion to any exciting cause and tending to become more and more independent of any such external agency. The patient begins gradually to lose interest in his former pursuits and pleasures, he shuns society, retires within himself, and gives way to morbid introspection and gloomy forebodings. For a time there may not be much noticeable alteration in the conduct of the sufferer; he retains at first

[1] Read before a meeting of the Border Counties Branch of the British Medical Association at Penrith, May 31st, 1895.

Digitized by Google

sufficient self-control to keep his troubles to himself—he knows they are morbid and have no real basis. In course of time, however, the mental aberration becomes more marked, he grows more and more unfit to pursue his ordinary avocations, the increasing difficulty of thought and of all mental work begets a feeling of resistance to the outer world, and hence originate the painful delusions which are so frequent in melancholia. In only 30 per cent. of the cases of melancholia treated at Garlands Asylum during the twenty-seven years from 1865 to 1891, inclusively, has there been simple depression without the presence of distinct delusions; in the remaining 70 per cent. delusions were more or less prominent; of course, in the large number of mild cases that never require asylum treatment there is a much greater proportion of cases of simple depression. According to the degree of mental depression, cases of melancholia have been artificially grouped into different varieties, as simple melancholia, hypochondriacal melancholia, delusional melancholia, and so on; but such subdivisions are purely arbitrary. All cases begin as simple depression and delusions are gradually evolved as the disease progresses; these at first are slight and fleeting, but gradually become more fixed and unchanging. The delusions of melancholiacs vary greatly in character. Delusions of suspicion and persecution are very common: the patient fancies that all his relatives and neighbours are in league against him, that he is being robbed of his property, or that his food is poisoned; in other cases some unseen agency is suspected to be at work—e.g., he fancies that electricity is played on him by invisible people. Very frequently the delusions refer to the spiritual welfare; the patient asserts that he has been very wicked, that he has committed the unpardonable sin, and that he is lost for time and eternity. In many cases the patient's whole attention is concentrated on the state of his bodily health; these form the group of hypochondriacal melancholia; such patients frequently exhibit an intense craving for sympathy and are constantly pouring forth lengthy statements of their imaginary maladies, some of the details being loathsome in the extreme. They complain that their bowels are never moved and they constantly clamour for aperients, or their throat is blocked up, or their stomach is gone, and so on. Some hypochondriacal melancholiacs talk much of putting an end to their woes by suicide, but they seldom make genuine attempts at self-destruction. In addition to other delusions, hallucinations of the special senses are frequent in melancholia. Hallucinations of hearing are most common; the patient hears voices mocking him, accusing him of crimes or inciting him to suicide. Next in frequency are hallucinations of sight; he is troubled by flashes of light or sees visions of various kinds. More rarely there are hallucinations of taste or smell; the patient complains of a persistent bad taste or of horrible odours. Some melancholiacs (often more chronic cases) pass into a state of great motor restlessness and excitement; they roam up and down wringing their hands, beating themselves about the body, loudly bewailing their fate, moaning and groaning continually. One such case in Garlands Asylum at present constantly declaims in somewhat the following strain: "Oh, what a fool I've been, I'se nought but a bit o' skin, I've no stomach, no bowels," and so on. This is the condition called melancholia agitans. Again, in some cases the depression passes into stupor more or less complete; the patient becomes more and more oblivious of surroundings till a state of complete apathy is reached; the expression is vacuous; no notice is taken of anything and no replies are given to questions; in extreme cases saliva dribbles from the mouth; at the same time there is vascular paresis, and the extremities become clammy and cold. There are two varieties of stupor: (1) melancholic stupor or melancholia attonita; and (2) inert or anergic stupor, or acute dementia. Melancholic stupor is characterised by the presence of some fixed delusion which absorbs the whole attention; there is a concentrated self-absorbed expression; it is often combined with great muscular resistiveness to all passive movements; after the stupor passes off the patient can often give a clear, connected account of all that happened while he was in the stuporose condition. Inert or anergic stupor is often the sequel of melancholic stupor; the patient is completely fatuous, lives a purely animal existence, and pays no attention to the calls of nature; there is no muscular resistiveness, but there is often a cataleptic condition with a tendency to maintain any position in which the body may be placed; there are no delusions; if recovery takes place there is no memory of anything that occurred whilst the stupor lasted. Such are the main varieties that melancholia may assume. The suicidal impulse is present to a greater or less degree in a large proportion of the cases. Out of 730 cases treated in Garlands Asylum it existed in over 65 per cent.; more than half of the melancholiacs who had this tendency had made one or more actual attempts at suicide; the remainder had only threatened it. The proportion of suicidal cases was 11 per cent. higher amongst the males than amongst the females; this relationship of the two sexes is still more marked with regard to suicides outside of asylums, for, according to Morselli,[2] "in every country the proportion of suicides is one woman to three or four men." Cumberland holds an unenviable position amongst the English counties with regard to suicide. Morselli[3] tabulated the suicides in every county in England and those in North and South Wales for the years 1872–76, and showed that Cumberland had the fourth highest rate, the annual average of suicides in this county being 96·2 per million inhabitants; in North Wales, where the rate was the lowest, the proportion per million was 36·7; and in Rutlandshire, which had the highest rate, the proportion was 153·9. Westmorland had a proportion of 58·3 per million inhabitants. The bodily symptoms of melancholia are characteristic. There is a condition of lowered vitality and anæmia, the complexion is muddy, the appetite is poor, digestion is impaired, and the bowels are torpid; the muscles are flabby, and there is a lack of vigour in all movements; neuralgic pains are often complained of at the onset, and sleeplessness is a most distressing feature. In many cases there is in addition some distinct organic disease, which may, indeed, be the exciting cause of the mental depression. Such a concomitant has existed in 29 per cent. of the cases of melancholia treated in Garlands Asylum. Phthisis pulmonalis was the disease most frequently associated with melancholia; it was present in almost 10 per cent. of the total number of cases; heart disease was present in almost 8 per cent. of the cases; whilst cancer and various other bodily diseases existed in smaller proportions of cases.

Causation of melancholia and suicide.—By far the most important factor is that of hereditary predisposition. The tendency to the mental disease is inborn and only lies dormant till at some critical period of life it is called into active existence. The cause popularly ascribed for an attack is usually just the spark which sets the train in action. Some bodily ailment or some mental shock which would produce no mental disease in a person with a healthily constituted brain is sufficient in those with hereditary mental taint to induce an attack of depression of a severity out of all proportion to the strength of the exciting cause. These immediate or exciting causes are most frequently of a physical nature; in considerably over half of the cases of melancholia treated in Garlands Asylum the attack had been preceded by some agency through which the general health had been lowered; included amongst these physical causes is intemperance in drink, which preceded the attack in 11·5 per cent. of the total number of cases. In about one-third of the cases the mental depression had been preceded by some trouble of a moral or mental character which was assigned as the cause; even in some of these cases, however, there was in addition some physical disorder preceding the attack; business anxieties constituted the most common moral cause in men, and domestic affliction in women. Considering now the question of hereditary transmission, there can be no doubt that melancholia is pre-eminently a hereditary disease. Hereditary predisposition was ascertained in over 38 per cent. of the cases of melancholia treated at Garlands Asylum during the twenty-seven years from 1865 to 1891, and undoubtedly it really existed in a much larger proportion of the cases. The relatives of the insane are often very loth to admit the fact that there has been previous insanity in their family, and, on the other hand, many of the poor are unable to give much reliable information about their ancestors for more than one generation back. It is an unfortunate thing for the race that attacks of melancholia are so curable and that individuals with this tainted constitution are allowed to marry and to propagate a degenerate stock, thus causing a more widespread deterioration of the race. Many of the country districts of Cumberland and Westmorland have only recently been opened up into free communication with the outside world; there for

[2] H. Morselli: Suicide, second edition, p. 189. [3] Op. cit., p. 46.

Digitized by Google

generations intermarriage has been going on to a most unhealthy and unnatural extent, with the result that the defects in the stock are further disseminated and intensified in each succeeding generation. The racial characteristics of the Cumbrians also foster the prevalence of melancholia. Remnants of old superstitions abound in many country districts, the inhabitants have not a superabundant supply of animal spirits, and they are often prone to look on the dark side of things; any little extra worry or some trivial bodily ailment is apt to upset their mental balance and produce undue depression or an actual melancholic attack. The inherited mental taint which predisposes to melancholia and suicide need not necessarily be derived from insane parents, it is an evidence of an unsound stock, and there may have been no actual insanity in the family for some generations back. Further, the unsoundness of the stock may not have previously exhibited itself as insanity at all, but as some allied nervous disorder, such as epilepsy, neuralgias, chorea, spasmodic asthma, &c. Drunkenness is a fertile source of race degeneration, and the victims of melancholia and suicide often have an alcoholic family history, though there may have been no previous insanity in the family. As already mentioned, outbursts of alcoholic excess also precede and act as the exciting cause of attacks of melancholia in a considerable number of cases. Alcoholism thus exerts its baneful effects, not only on the drunkards themselves, but equally, if not more, on their descendants. Then it has been attempted to prove that there is a relationship between the state of morality in a district and the amount of suicide in it. The state of sexual morality in any district can be roughly gauged by observing the proportion of illegitimate to total births. Dr. S. A. K. Strahan, in his book, "Suicide and Insanity," quotes a table of the suicidal and illegitimacy rates in the English counties; in Cumberland the illegitimacy rate is very high, 76 out of every 1000 births being illegitimate; this rate is only exceeded in one county in England, Shropshire, where the illegitimate births are 82 per 1000; in Westmorland the rate is 70 per 1000. The high rate of illegitimacy thus corresponds in Cumberland with the high proportion of suicides; but, as Dr. Strahan points out, there is not a similar correspondence in other counties in England. Thus Rutlandshire, which has the highest suicidal rate in England, only comes nineteenth on the list as regards illegitimacy; while Shropshire, which has the highest rate of illegitimacy, only comes thirtieth in the list of counties arranged according to frequency of suicide.

Course and terminations of the attack of melancholia.—Of the cases of melancholia admitted into Garlands Asylum from 1865 to 1891 inclusively, 58 per cent. terminated in recovery. As a rule recovery takes place gradually, and along with the improvement in the mental state there is a corresponding improvement of the bodily health; it is a favourable sign when the patient begins to put on fat. The duration of the attack in cases that recover varies greatly; of the cases that recovered in Garlands Asylum, 10 per cent. were discharged within three months, 47 per cent. within six months, 66½ per cent. within nine months, 73 per cent. within twelve months; 87 per cent. recovered in less than two years, leaving 13 per cent. who took more than two years to get over the attack. In some cases recovery takes place after a very prolonged attack of melancholic depression; three of the series of cases at Garlands Asylum recovered after having been in the asylum more than ten years; so long as the case remains one of pure depression, without marked impairment of the intellectual powers, there is always a chance of recovery; this constitutes one of the hopeful features of melancholia. Of the cases that do not recover a considerable number remain throughout life in a chronic melancholic condition; the face retains its expression of woe, the sufferers may still give utterance to mournful statements and painful delusions, but these are largely the result of habit; the physiognomy suggests more mental pain than is really felt; there is more loss of self-control than in the earlier stages, and there is a good deal of mental enfeeblement combined with the depression. Some cases pass into a state of mania, and a small proportion become demented; but melancholia is much less prone than mania to terminate in complete dementia. Twenty per cent. of the cases of melancholia treated at Garlands Asylum died without recovering from the mental disease. Phthisis pulmonalis was the most frequent cause of death, 22½ per cent. of the total number of deaths resulted from that disease. Gradual exhaustion from the melancholia without localised organic disease was the next most frequent cause of death (16½ per cent. of the total); in two other cases dying from exhaustion gangrene of the lungs set in before death and accelerated the fatal issue. Twelve deaths resulted from senile exhaustion, 10 from cancer, and various other bodily diseases caused the remaining deaths, with the exception of 6 which resulted from suicide. Three patients cut their throats (one of these had committed the act before admission to the asylum), one patient hanged himself, one was killed by jumping from a lofty window in an attempt to escape, and one patient, while out on trial for a month, had a relapse and committed suicide on the railway. Only two of the suicides were females; both cut their throats. Persons who have had one attack of melancholia are liable at some subsequent period of their lives to have a recurrence of the disease. Of the cases of melancholia admitted into Garlands Asylum 22 per cent. had had one or more previous attacks of mental disease. In a considerable number of cases melancholia has been preceded by a former attack of mania, and in other cases mania may attack persons who have previously suffered from melancholia.

The prognosis of an attack of melancholia is on the whole favourable. Contrasting the recovery rate of the cases of melancholia treated at Garlands Asylum with that of the cases of mania during the same period, it is found that the proportion of recoveries has been 4 per cent. higher in the former than in the latter. The following factors are of importance in forming a prognosis:—1. The age on attack. The statistics of Garlands Asylum show that melancholia is chiefly a disease of middle and advanced life; it is proportionately much less frequent than mania before the age of thirty, and considerably more frequent after sixty. The younger the patient is when attacked by melancholia the greater are the prospects of recovery, and the recovery-rate gradually falls as the age on attack increases; but even when melancholia comes on in advanced life there is still a fair chance of recovery. 2. Sex. In Cumberland and Westmorland melancholia seems to attack the female more frequently than the male sex; in the cases of melancholia admitted into the asylum females were in the proportion of 118·5 to every 100 males, while in the general population of the two counties there were in 1891 only 102·3 females to every 100 males. Of the male melancholiacs admitted 60·5 per cent. recovered, compared with 55·8 per cent. of the females, so that in this district the chances of recovery from melancholia are slightly greater in the male than in the female sex. 3. Hereditary predisposition. In hereditary cases attacks of melancholia are apt to come on earlier in life than in non-hereditary cases; the individual attacks are more curable and the death-rate is lower, but relapses are more frequent. 4. Cause of the attack. When the exciting cause of the depression has been of a temporary or removable nature the chances of recovery are greater than when it has been brought on by incurable bodily disease or by prolonged mental worries and suspense, endured it may be for years before the mind has finally given way. The melancholia of the heart-broken girl after a love disappointment is, as a rule, transient and short-lived; the depression that follows a drinking bout is usually quickly recovered from, frequently to relapse when supervision is withdrawn and the evil habit is returned to; on the other hand, the melancholia that is associated with a serious bodily disease, such as phthisis pulmonalis, often ends only with death. 5. Mode of onset. The prognosis is more favourable when the onset of the mental depression is rapid, and is in contrast to the natural temperament of the individual, than when the melancholia sets in deliberately or is simply the climax of the gradual evolution of an inherently gloomy and joyless disposition. 6. Duration of the attack before treatment is commenced. The sooner the patient is placed under proper care and treatment the greater are the chances of recovery. 7. Severity of the attack. Simple depression is much more curable than melancholia with delusions. If the delusions are fixed and unchanging, and especially if they are of a visceral nature or if hallucinations are present, then the outlook is less hopeful. In cases where there is extreme restlessness and acute delirium in patients of feeble constitution the prognosis is extremely grave. Other serious signs are continued bodily wasting, persistant refusal of food, and long duration of the attack in spite of treatment. It is well to remember, however, that so long as there is no marked impairment of the intellectual powers there is always the hope of recovery, even though the depression may have lasted for years.

Digitized by Google

Treatment of melancholia.—Mild cases of melancholia are more amenable to home treatment than most other forms of insanity, and many such cases can be, and are, treated at home throughout their whole course. The patient's friends notice his increasing abstraction and unhappiness, but, apart from a feeling of solicitude for him, they themselves are not appreciably inconvenienced, and consequently they are less anxious about having him removed from their midst. On the other hand, the onset of mania is generally more rapid; the individual suffering from this disease much sooner becomes actively objectionable to those in his vicinity; his restlessness, his loquacity, his noise and combativeness, all combine to make him an uncongenial associate, and quickly reconcile his relatives to his removal elsewhere. In confirmation of this statement an examination of the admissions into Garlands Asylum for the past year shows that on an average the duration of the attack of insanity prior to admission to the asylum has been considerably greater in the cases of melancholia admitted than in those of mania. The period at which a melancholic patient is sent to an asylum is also dependent to a considerable extent on his pecuniary position. A case of melancholia, which in the upper and middle classes might be treated at home throughout the whole of its course, would, if it occurred in a working-class family, be sent to an asylum as soon as the individual was so far affected as to be unable to continue his occupation; he ceases to earn a livelihood for himself and becomes a burden upon the other members of the household which they are unable to bear; and, besides, it is not possible in the houses of the poor to provide the adequate accommodation or supervision for the treatment of such cases. Corroboration of this general statement is afforded by an examination of the pauper and private admissions of cases of melancholia into Garlands Asylum; the average duration of the attack prior to admission has been considerably greater in the private than in the pauper cases. It may be well here to briefly summarise some of the points which must be kept in view in deciding on the question of home or asylum treatment. Over twenty years ago Dr. Clouston read a paper on this subject before the Border Counties Branch of the British Medical Association, and most of what he said then still holds good to-day. Each case must be decided on its own merits. The physician must take into consideration the nature and severity of the symptoms and the circumstances and surroundings of the patient. Many mild cases can be satisfactorily treated at home, where the patient will have the kind care and attention of his friends. In more advanced cases, however, suspicion and distrust of all friends and relatives often become distressing features, and then the surroundings and associations at home may aggravate the disease; in such cases removal from home is often necessary before any alleviation of the symptoms can take place. Where there is persistent refusal of food and medicines, unless the medical man can attend several times a day to feed the patient artificially, asylum treatment is demanded. If the suicidal impulse is strongly developed, then the asylum is much the safest place for the patient; however careful friends and attendants may be, there are always far greater opportunities for committing suicide at home than in an asylum. Even mild cases of melancholia may have to be sent to an asylum if after prolonged treatment at home recovery does not set in; the complete change of surroundings, the regulated life and the amusements of the asylum, will often produce the desired improvement. As already indicated, the patient's means must be taken into account; if special attendants have to be provided home treatment becomes too expensive for those with small incomes, and for this reason removal to an asylum may be necessary. It is extremely difficult to treat a bad case of melancholia in a large town, and if the friends are unable to send the patient with proper attendants to a quiet country place, an asylum, being situated, as it usually is, in the country, is more suitable. Where the case is one at all suited for home treatment, it is always best for all concerned to keep the patient out of an asylum so as to avoid the stigma, unjust though it be, which is attached to those who have been in an asylum or who have had relatives under treatment there. In the treatment of melancholia the first indication is to combat any agencies which may have induced or may be fostering the mental depression. All undue mental effort and all harassing brain work must be stopped. In the young too much attention to religious exercises should be forbidden; they should not be allowed to attend too many prayer-meetings. If possible the patient should be removed from depressing surroundings. In mild cases change of scene is advisable—removal to a quiet country district, with life in the open air as far as possible and outdoor recreations; or he may go with a cheerful companion for a course of travel by easy stages. The diet is of great importance; the patient should have abundance of fat-forming food, plenty of milk, butter, eggs, and easily digested food; too much butcher's meat should be avoided, and the cooking should be good so as to tempt the appetite. In cases where food is absolutely refused artificial feeding by the stomach-tube must be resorted to twice or thrice daily; the simplest and best form of liquid diet to be given in this way is a liquid custard made with milk, sugar, and several eggs; soup may also be given, and if feeding has to be continued for a long time meat and vegetables may be pounded up in a mortar with beef-tea and administered by the tube; along with the food malt extract, stimulants, or drugs may also be given by the tube. In addition, general tonic treatment should be employed; iron, quinine, strychnine, and vegetable bitters are often serviceable. Attention must be paid to the state of the bowels, constipation being often a troublesome symptom. Stimulants are often useful when the health is much run down, especially malt liquors, such as beer or porter; in some cases a little whisky at bedtime aids sleep. Much distress is often caused by sleeplessness; this can frequently be remedied by getting the patient to take plenty of outdoor exercise, and a good meal shortly before bedtime frequently acts as an excellent soporific; if these measures are not sufficient it becomes necessary in addition to administer sedatives. At Garlands Asylum paraldehyde has proved in many cases a most efficacious hypnotic; bromide of potash, sulphonal, or chloral may also be used to procure sleep. In excited cases of melancholia it often also becomes necessary to give sedatives during the day. Sulphonal given in small doses twice or thrice daily has proved very serviceable in cases of melancholia agitans; it subdues the motor restlessness, induces sleep, and promotes recovery, but its action must be carefully watched, as when its use has been long continued it has been found in some cases to produce very deleterious effects on the blood. The bromides may also be used as day sedatives, and they may advantageously be combined with tincture of cannabis indica. Opium at one time was extensively employed in the treatment of melancholia, but it has been found to produce injurious effects on the system. If there is the slightest suspicion of suicidal longings the patient must have constant companionship with someone who must never allow him out of his sight. A suicidal patient must not be allowed to sleep in a room by himself; all articles, such as razors, guns, &c., which can suggest the idea of suicide should be removed. In cases that require to be sent to an asylum the mere change of scene and surroundings, the regulated life, the discipline and the amusements of the asylum, and the removal from relatives and friends, whose attentions often increase the patient's distress, are of themselves sufficient in many cases to initiate a quick improvement in the mental state. The opportunities afforded for attempts at suicide are fewer. The patient is given open-air exercise sufficient to promote appetite and to improve the tone of the system, but not unduly fatiguing. The diet is carefully attended to; tonics and stimulants are prescribed when necessary, and sedatives are made use of. An endeavour is made to get the patient to take part in games and amusements, and to employ himself usefully. The general object of treatment, in short, is, by improving the bodily health and rendering the environment of the melancholiac as agreeable as possible, to substitute a feeling of well-being for the unhappy emotions that have laid hold of him. As regards prophylaxis in melancholia, great care must be taken as they grow up of children who have a hereditary tendency to this disease; they should be made to partake largely of fattening foods, should live much in the open air, and should not be forced to work too hard at school; they require special attention at the time of puberty and during adolescence. Those who have already had an attack of melancholia should live well-regulated lives, avoid exciting occupations and arduous brain work, and take a good holiday in the country whenever they feel a little run down. They should always endeavour to have a good night's sleep, and whenever they begin to pass sleepless nights should at once discontinue all work and go into the country.

A CASE OF

FRACTURED BASE OF SKULL WITH LACERATION OF BRAIN, ACCOMPANIED BY SUGAR AND ACETONE IN THE URINE.

BY E. BROMET, M.R.C.S. ENG., L.R.C.P. LOND.,
SENIOR HOUSE SURGEON, WEST LONDON HOSPITAL;
AND
J. G. PARDOE, M.B., C.M. ABERD., M.R.C.S., L.R.C.P. LOND.,
ASSISTANT HOUSE PHYSICIAN, WEST LONDON HOSPITAL.

THE following interesting case came under notice at the West London Hospital in July last. The patient, a police sergeant, was on night duty on Friday, July 12th. On Saturday morning, the 13th, he returned to the police station at the usual time, and there gave a written report of his night's work. From this report it was shown that he had met police constables about every hour during his rounds. Nothing strange or peculiar in his manner was noticed by any of these men, and the inspector to whom he made his night's report said he was apparently in the best of health. The patient had some food and then went to bed about 10 A.M. on Saturday morning. During the daytime he got out of bed on several occasions and went downstairs to the watercloset. Later in the day a police-constable who shared the same bedroom noticed that the patient was not quite himself, that he appeared irritable when spoken to, and later seemed "drowsy and bilious." The divisional surgeon was called in to see him at night and diagnosed the case as epilepsy. Two bruises were detected by the surgeon, one behind the left ear and the other at the inner canthus of the left eye. These bruises he supposed to have been inflicted during the epileptic fit, and his present drowsy condition to be one of post-epileptic coma. The patient was a strong, athletic man, who up to the present time had always enjoyed good health. On Sunday night, July 14th, he was admitted into hospital, when he lay on his side with closed eyes and breathing easily. He violently resented any attempt at examination, and answered incoherently when roused by shouting in his ear. The pupils were equal and normal. The pulse was 56, full and strong. He was very restless. The lungs, heart, and other organs were apparently healthy. There was no paresis. A bruise was noticed behind the left ear over the mastoid process, and another at the inner canthus of the left eye. The specific gravity of the urine was 1030. There was no albumin, but strong sugar reaction. The patient was very restless during the night, and made several attempts to get out of bed. He had incontinence of urine. On Monday, the 15th, he was quite unconscious. The restlessness had passed off. There was no paresis. The swelling and bruising behind the left ear were much more marked. Sugar was present in the urine. The coma becoming more pronounced, a consultation was held in the afternoon, when the question was raised as to whether the symptoms, in the absence of any history of injury, were not due to post-epileptic or diabetic coma. It was decided, however, to make an exploratory operation. At 6.30 on Monday evening, under an anæsthetic, Mr. Bidwell operating, an incision was commenced immediately behind the mastoid, and on turning down a large square flap an extensive fracture was discovered. This fracture was followed, and was found to extend from the centre of the lambdoidal suture behind to the posterior part of the zygoma in front, traversing the occipital (slightly) squamous portion of the temporal and parietal bones, and also part of the zygoma. The fracture was fissured and splintered. Mr. Bidwell removed the splintered portion of bone, together with some more bone around it, in the neighbourhood of the middle meningeal artery, and on opening the dura mater a large amount of lacerated brain substance mixed with fluid blood and small clots escaped. The mid-meningeal artery was intact, but one of its posterior branches was ruptured. As further operative treatment was considered inadvisable the wound was closed. Although the patient appeared to improve somewhat after operation, in a few hours the coma began to deepen. Paresis set in, commencing first on the right side. Some urine was now collected and tested. Sugar was present, and with it acetone, the tests on this occasion being carried out by Dr. Archibald Garrod. This was the first time on which the acetone test had been applied. From this time until his death the patient gradually got weaker, and died at 12.30 A.M. on July 17th, three days after admission. About six hours before death some urine was collected and tested, when it was found that the sugar and acetone had disappeared.

Necropsy.—At the post-mortem examination the following lesions were found. On removal of the scalp a fissured fracture was seen, extending from the posterior end of the zygoma to the middle of the lambdoidal suture. From a point about two inches behind the commencement of this fracture another ran across the middle fossa to the foramen ovale, and thence to the foramen lacerum medium. The trunk of the middle meningeal artery was uninjured, but a small posterior branch was torn across. A smaller fracture extended from the foramen ovale to the sphenoidal fissure. Rather below the groove for the left lateral sinus another fracture was traced from the end of the main fracture almost to the jugular foramen. A clot was lying loosely along this fracture, but the lateral sinus was apparently uninjured. The mastoid cells were full of clot, but the middle ear had escaped injury. The left hemisphere of the brain had sustained most extensive injuries, and the right hemisphere also had not escaped, the lesions here being apparently due to contre-coup, the anterior extremity of the second right temporal convolution being much lacerated, the laceration extending from the surface into the fissure of Sylvius, in which there was a large clot. The left temporal lobe had sustained an even more severe injury, the anterior extremities of the first and second left temporo-sphenoidal gyri being reduced to a pulp. The posterior extremities of the second and third temporo-sphenoidal gyri were in a similar condition, being immediately under the depressed piece of bone which was removed at the operation. In the left frontal lobe there was a large laceration with much blood clot on the orbital surface and another at the apex. In the right frontal lobe there was a similar condition on the orbital surface and another laceration at the junction of the external and orbital surfaces. The basal surfaces of both frontal lobes were practically reduced to cysts. Elsewhere, both on the right and left hemispheres there were numerous small subarachnoid effusions and a small laceration involving the third left occipital convolution. There were adhesions of the right pleura. All the other organs were healthy.

Remarks.—This case appears to us of considerable interest both from a medico-legal and from a purely medical aspect. Firstly, the absence of any history of injury does not negative the view that the patient suffered violence. In hospital practice we are well acquainted with cases of fracture, especially of the posterior fossa, in which the patient has walked up to the hospital on the following day or later, and has complained of headache without remembering any accident. Many such cases have been recorded in THE LANCET, the most remarkable being that of a man who fell on his head, but was not stunned, and had no symptoms for fourteen days, when he became comatose and died the next day. An extensive star-shaped fracture in the left mastoid was discovered at the necropsy. In another case a man aged forty fell thirty-five feet, alighting on his feet. He felt shaken, but was not stunned, and he went to work the next day. He had no symptoms until the fourth day, when he complained of pain in the ear. This, however, did not prevent him following his occupation. Three weeks after the accident he had severe headache and paralysis of the right sixth nerve. He remained in the same condition for four months, when he had very violent delirium and died within twenty-four hours. The necropsy disclosed a comminuted fracture of the petrous portion of temporal bone. Secondly, we know that glycosuria does occur in head injuries. But we are not aware that acetone has ever been found in association with the so-called "traumatic glycosuria." The urines in these cases of head injuries are not often tested, owing chiefly, no doubt, to the fact that incontinence is generally present. Thirdly, were the acetone and glycosuria in this case of any value from a medico-legal point of view—i.e., was the injury due to a fall while the man was in a state of diabetic coma, or were the glycosuria and acetone secondary to the trauma inflicted on the brain? Fourthly, if the case were one primarily of diabetic coma, would the acetone and sugar in such a case disappear several hours before death, as happened in this case? Lastly, would it

Digitized by Google

be possible for a man apparently in the best of health and without any history or symptoms whatever of diabetes to suddenly develop the coma of diabetes? These are, we think, important points to consider in giving evidence in such a case before a jury. In this case the police ridiculed the idea of foul play. The coroner's court returned an open verdict.

THE PREPARATION OF ANTIRABIC SERUM AND THE METHOD OF DETERMINING ITS STRENGTH.

BY PROFESSOR GUY TIZZONI AND DR. EUGENE CENTANNI.

(Continued from page 664.)

III.—MODE OF DETERMINING THE PROTECTIVE POWER OF THE ANTIRABIC SERUM.

IT was evident from the results of the preceding experiments upon rabies executed in our laboratory that the importance of an exact method of determining the dose to be used against this infection was very great, it being observed that a determinate quantity of serum was alone of value in the neutralisation of a given quantity of virus. In our successive studies the difficulties which from time to time were met with in determining the power of a given serum obliged us to return to the question of dosage and to ascertain the various conditions whereby we might be able to obtain constant results. Moreover, since our researches had not simply a scientific aim, but contemplated an eminently practical one, it is clear that, until the conditions indicated had been complied with, it would have been very imprudent to pass to the application of our remedy to man. The general lines of our method follow those actually in use in serum-healing, but in their application to rabies, which is quite a special infection, they necessarily undergo some modification and additions, which we shall now proceed to specify.

1. DOSE OF THE VIRUS.

a. Importance and difficulty of the determination of the dose of the virus in rabies.—In our preceding research we unfortunately had not taken the dose into account. We limited ourselves to the production of the infection as is commonly done in antirabic institutes—with a highly variable material, regulating the dose by the concentration of the emulsion and by the quantity injected. To graduate the power of the infection we make use only of virus—the fixed virus and the canine virus. It is certain, however, that in rabies the question of the quantity of the virus which is used in the test infection ought to have no less importance than the differing strength of the virus itself, as has already been reliably demonstrated in the two typical infections upon which serum-healing has been founded. We know, in fact, that in tetanus the smallest fraction of the established dose of the poison suffices to kill, because the animals die without being affected at all by the injections of the serum, which would otherwise have surely saved them against the exact dose of the poison. If these difficulties are found, then, in experimenting with soluble and therefore exactly measurable toxic substances, how much greater ought they to be when in the material employed for experimental infection one has to deal with living germs—that is, instead of with an intoxication, with an infection properly so-called, and with an infection of which we do not know the active agent or the manner of artificially cultivating it. In the intoxications, the quantity of antitoxin introduced into the body remaining constant, if there is any excess of injected poison the least quantities of toxine not neutralised by the serum are manifested by morbid phenomena proportional to their dose. In the infections, on the other hand, including rabies, as will be demonstrated later, a small quantity of germs not rendered inactive by serum, proceeding to develop, ultimately kill the animal (after some considerable time perhaps)—in general, as much later as the residual quantity of the virus is less. Although the toxic infection can be utilised for the determination of the serum, in the case of rabies the inquiry must be restricted to the quantity of serum capable of completely neutralising in the body a given quantity of virus, without, that is, the animal presenting any morbid phenomena, its sole effect, therefore, being to postpone a fatal result.

b. Directions for the preparation of the infecting material.—In rabies we must make use of a natural cultivation of the virus which contains a large quantity of foreign materials, all constituents of the nervous system. As yet there is no artificial way of making a cultivation of the virus of rabies; this constitutes an inconvenience, especially with the canine virus, which is extremely variable in intensity, according to its derivation. The fixed virus we may consider is certainly relatively, if not absolutely, more constant. With this last virus the activity can also be varied by several factors—the individual condition of the animal; the rapidity with which it dies; the part of the central nervous system which is chosen for the infection; and, lastly, the period of preservation in glycerine. We have tried to reduce to a minimum all these inconveniences. For the fixed virus we have always allowed the animals to die spontaneously, because, having killed one of them, actually *in extremis* and for a long time paralytic, the dilutions, usually active, were unsuccessful. To obviate all mistakes which could arise from the diverse quantity of germs contained in the various regions of the nervous system we have always taken the material from the same part—that is, from the bulb. From the great frequency with which we made our experiments, not always having the opportunity of practising infections from head to head, we have often been obliged to have recourse to infections with virus preserved in glycerine. But, since the duration of this preservation is not indifferent in the determination of the degree of virulence, we have always tried to make use of a virus which had been collected for not more than three or four days. In the case of the virus "da strada" we have not been able to put into practice all these precautions—unassociated as we are with any anti-rabic institution. We have usually chosen a virus which killed in from sixteen to twenty days, obtaining results which would represent a mean between those obtained with a virus of varying derivation. However, the canine viruses have been rejected as being either too weak or too energetic, and we have had among the last of these one which gave the first signs of disease at the eighth day and death at the eleventh. The material was preserved like the fixed virus, but rather longer, we having observed that the differences which can come from its gradual attenuation, by its preservation for three or four months in glycerine, are less marked than those which we come across when having frequent recourse to the virus of another animal. For the rest, along with every series of experiments numerous controls are always made as a guarantee that the material employed had preserved its virulence to the desired degree. The virus of rabies which is found in the nervous system presents another disadvantage compared with bacterial culture, and much more as compared with soluble toxin—it exists in a solid and insoluble form. It is necessary, therefore, to reduce it to the state of greatest sub-division, whereby the injection is made to represent a condition of mean stability. To this end we take a piece of virus always in a quantity of 10 grammes, exactly weighed, and break it down for a long while in some combination of fluid, in the common conical graduated glasses, by means of a rod of glass polished with emery; it is then slowly mixed with the desired quantity of sterilised distilled water.

c. Choice of the most suitable dilution of the canine virus.—It is known how in the rabid nervous system the virus may be highly concentrated, so that it is necessary to make certain dilutions before being able to follow the varying duration and intensity of the morbid phenomena. And, further, we meet with extended series of dilutions from which we obtain a progressive lengthening in the period of incubation before any effect whatever appears. These facts have been demonstrated specially upon the fixed virus by the experiments of Pasteur and of Babes. It is worth noting that in the emulsion of virus which is commonly used to infect rabbits one finds a multiple of the minimum fatal dose of the same virus, a multiple for several reasons variable, and which would render useless any precise measure it might be desirable to use in testing the anti-rabic serum. We have chosen for the infection of our rabbits a dilution always definitely determined, and however stronger the emulsion it always produced death without delay after the ordinary period of incubation. Wishing to have a means of measurement which should demonstrate not merely the higher degrees of the power of the serum we were obliged to keep the virus at a dilution not too concentrated. In the

Digitized by Google

virus "da strada" these experiments to determine the most suitable dilution have been made with a material which in the concentrated emulsion gave the first phenomena at from the eleventh to the fourteenth day, and death at from the sixteenth to the twentieth day. It will be understood that of the final dilution there was always injected a known quantity exactly proportional to the weight of the animal—that is, 0·013 c.cm. (one-fourth of a drop) for every kilogramme. The results of these experiments are collected in the following chart.

TABLE VIII.

Number of register.	Weight of rabbit in kg.	Degree of dilution.	Equivalent in virus.	Results.	
				First Signs.	Death.
43	1·430	Virus: water 1 : 50	0·00026 gr. per kg.	15th day.	18th day.
39	1·410	1 : 100	0·00013 ,, ,,	17th day.	20th day.
52	1·700			14th day.	22nd day.
44	1·690	1 : 200	0·000075 ,, ,,	—	91st day.
45	1·110	1 : 500	0·000026 ,, ,,	Survives. Four months' observation.	

Experiments similar to the preceding have been repeated with virus taken from a second dog, which produced, however, death after a period of incubation of from sixteen to twenty days. Thus in this case we have found that the dilution limit before any delay whatever in the incubation period was obtained was represented by 1 in 100. We, however, in order to remain within the bounds of a safe injection, and in order to cover the small inevitable variations in the strength and in the distribution of the virus, have avoided the extreme dilution, adopting for the subdural infection the double degree—that is, the dilution 1 in 50 (10 grammes of virus in 500 c.cm. of water). As of this dilution we injected 0·013 gramme per kilogramme of the body weight of the animal, we had to inject for every kilogramme of the animal 0·00026 gramme (one-fourth of a milligramme) of pure virus.

d. Choice of the suitable dilution of the fixed virus; advantage of the fixed virus over the canine virus in estimating the power of the serum.—Notwithstanding that our researches upon rabies were well advanced and combined a degree of exactness and desirable safety—we now think we find ourselves completely free from any inconvenience in the determination of the power of the serum—it was still necessary to test our remedy against the most active virus of rabies to be obtained. The determination by means of the canine virus demands above everything a great loss of time, not only as regards the regular periods of incubation, but especially as regards the long periods of subsequent observation to which it was necessary to subject these animals. For if the least quantities of virus remained not neutralised, as we pointed out a little while ago, we were always obliged to wait for a very long time in order to see whether the rabbits died from rabies—sometimes as long as four months. From this it will be understood how, wishing to make a complete series of graduated experiments in order to establish the power of a given serum, we might have to keep a considerable number of animals under observation for several months, thereby losing precious time, since in this period the criterion for passing to another series of experiments was wanting. On the other hand, with the fixed virus we can, as early as the fifth day, infer the result of the experiment from the diminution in the weight, and in a certain number after from fifteen to twenty days such a result can be definitely declared, since the virus is either quite destroyed, or the smallest quantities which remain not neutralised, when a virus so energetic is used, cause death comparatively early. It is on this account that, while great delays in death, according to the dose and the quantity of serum employed, are not rare when we make the determination with the virus "da strada" instead of with the fixed virus, we have, in a large number of experiments, seen death protracted over the limit indicated in one case only. From the rapidity in the determination of the strength of the serum there is also derived an economic advantage not to be despised, as one is no longer obliged to keep under observation the same series of animals and one is able to set aside for vaccinating material the nervous system of those animals which would have died in the trial of the serum after the infection with the fixed virus. But a most important consideration compelled us to find a still more suitable method of research. As we were obliged to supply our serum to various experimenters, it was necessary to find a common term of measurement in order that the repeated experiments might be comparable with our own, it being known how much the power of the virus of rabies "da strada" varies in different dogs. This continued efficacy can only be hoped for with the fixed virus; there is further, however, another advantage. As soon as our serum has been shown to be efficacious against the most active virus we shall be able to silence the possible objections to its application to man and to calmly await the practical test. For some time we continued to make attempts to confer immunity against the fixed virus by means of our serum; we were assured of the final success of these attempts, as we believed that in vaccination dealing with specific actions every vaccinating virus is of value to protect against itself. We were obliged ultimately with our serum to succeed in neutralising the virus which would be employed in vaccination. We have not, however, treated of the qualitative differences, although there was the difficulty, on the one side, of obtaining a serum so energetic as to counteract a virus so intensified, and, on the other hand, of fixing the dose of the fixed virus to be injected in such a manner as to have degrees of infection exactly determinable. Of course, our first experiments undertaken with serum not yet very strong and with an excessive quantity of the virus necessarily failed. We have undertaken these experiments successively, and our first care has been to determine the dose of the fixed virus to be injected. As we had already found for the virus "da strada," so also have we found, for the fixed virus, the larger dilution which would cause death to the animal without any delay. For the infection we have used the subdural method, and the quantity of emulsion introduced has always been 0·013 gramme per kilogramme of the weight of the animal.

TABLE IX.

Number of register.	Weight of rabbit in kilogrammes.	Degree of the dilution.	Equivalent in virus.	Death.
172	2·000	Virus: water 1 : 50	0·00026 gr. per kilog.	Eighth day.
151	1·600	1 : 500	0·000026 gr. ,,	,, ,,
152	1·600	1 : 1000	0·000013 gr. ,,	,, ,,
154	1·620	1 : 5000	0·0000026 gr. ,,	,, ,,
153	1·350	1 : 10,000	0·0000013 gr. ,,	,, ,,
160	1·570			Ninth ,,
171	1·790			Eighth ,,
158	1·850	1 : 20,000	0·00000075 gr. ,,	Ninth ,,

Repeating the same observation for a fixed virus obtained from another laboratory, we have found that the greatest dilution which regularly produced death without delay was one of 1 in 5000. In the experiments made with the first of these viruses we have, therefore, adopted the dilution of 1 in 10,000, and in those made with the second that of 1 in 5000. Of this we are particularly careful, because in controlling our material we have, first, the warning given in the determination of the greatest dilution in which the fixed virus with which one makes the trial gives fatal effects without delay, that this dilution is not constant for the various samples of fixed virus, even though these produce death in the regular term of seven days. Injecting 0·013 gramme of the dilutions for every kilogramme, the quantity of fixed virus which can be injected in the proportion of 1 in 10,000 corresponds to 0·0000013 gramme, and in the proportion 1 in 5000 to 0·0000026 gramme. We see, therefore, that with the virus of rabies, as with every other infection, the different cultures of it in equal quantities of volume and weight do not contain a material of a constant strength; in order, therefore, to determine the dose of a given cultivation we are compelled to have recourse, as is already done in the case of tetanus and diphtheria, to the measure of the pathogenic effects produced upon the animal organism. In our case we shall call the "infecting unit" the greatest dilution of a virus which in the dose of one-fourth of a drop per kilogramme of the body weight succeeds in causing fatal rabies without any prolongation of the normal period of incubation. We have thus the infecting unit for each of the two viruses—viz., for the

Digitized by Google

fixed virus causing death in from seven to eight days, and for the canine virus in from fifteen to twenty days.

e. The place and method in which we practise the infection.—To introduce the virus we make use of the smallest glass syringe with the finest needle, all exactly graduated to 0·026 c.cm. (half a drop), which corresponds to the dose of the emulsion per two kilogrammes, the mean weight of our rabbits. We have, in the course of our experiments, made use of two methods of infection—viz., the subdural in the neck and the intra-nervous in the sciatic nerve. For the subdural infection we follow the common course of making the needle slide somewhat horizontally for a certain distance between the bony walls and the dura mater before transfixing this last in a manner that the puncture is made beyond the trepanned area. In this way, after the virus is injected and the needle withdrawn, the opening left is compressed against the bony walls, and thus closed so that any regurgitation of the injected liquid is avoided, which, if it happened, would take away all value from the experiment. The infection by the sciatic nerve has been undertaken by us only in a few cases, nearly always comparatively with the infection by way of the neck. By means of this infection we approach much more to the natural mode of infection in man, and to the smallest mortal dose of the virus, inasmuch as the direct lesion of a large nerve trunk always represents a more serious lesion than any small bite. As it seems that the value of the infection in the sciatic nerve is not understood by all, and that the accuracy of the results obtained by this mode of infection is not generally recognised, we continue to assert, pointing both to our long experience and to the results obtained by others (Divestia and Zagari), which are recognised as being exact even in Pasteur's laboratory, that the injection of the virus of rabies into the sciatic nerve of the rabbit succeeds just as when the injection is made under the dura mater. This success is the fruit of careful management. Having laid bare the nerve and raised it with a blunt hook we introduce the needle by a long track into its thickness, parallel to the fibres and with lateral movements repeated both going and coming; we thus break and separate the nerve fasciculi in such a fashion as to form a long canal, which is soon filled with virus. We consider that we have thus overcome the objections raised to those among our experiments made by the intra-nervous infection method; as for the rest, basing our results always on a considerable number of experiments with relative control experiments, one was not invariably able to invoke for them an exceptional fate (reading *fato* instead of *fatto*). The sole difference which we have been able to note between the one form of infection and the other is that in the intra-nervous infection the course of the diseases is a little longer. In our experiments on the sciatic nerve—to put ourselves within the limits of the surely fatal dose, and regard being had to the smaller sensibility of the part—we have always employed a stronger solution than is used for the neck: That is, we have in the case of the virus "da strada" made the infection with the dilution 1 in 20 instead of that of 1 in 50, introducing a quantity almost equal to that used for subdural infection. For the fixed virus the dilution has been considerably greater—i.e., 1 in 1000—when we have experimented, as we shall see, with the direct protective method. The dose of the serum offers no difficulty. We have employed in our experiments both liquid serum and dried serum with identical results. All the calculations upon its power are made taking for a basis the liquid serum; between this and the solid, as we have said, there exists the mean relation of 13 to 1. In order to inject the smallest quantities dilutions are made with the physiological "normal" solution of chloride of sodium. The protective power in life is expressed by Behring's method—that is, the mean ratio between the number of grammes of rabbit protected by a c.cm. of serum. In the experiments *in vitro* the power is expressed by the ratio between a c.cm. of serum and the number of infecting units which it is capable of neutralising. As for the ways of introducing the serum, we have made use of the subcutaneous connective tissue of the back and the subdural space of the neck; in no case in this new series of experiments have we had recourse to intra-peritoneal or intravenous injection. With respect to the quantity of serum to be injected we have not been able to take as a rule the least quantity capable of neutralising a determined dose of virus, because (by reason of mistakes of which we have spoken earlier) such a quantity of serum was at one time shown to be sufficient, at another to be insufficient, to destroy every effect of the virus. Here it occurs to one naturally, not only to take into account the small variations which arise out of individual dispositions, but also to introduce a quantity of virus little if any greater than that absolutely necessary for the most easy and ready multiplication. On the part of the serum, also, there may be slight variations depending on the different rate of absorption when injected under the skin, and on the variable readiness with which the active principle comes to be assimilated by the tissues or destroyed and eliminated. In order to confirm these facts we shall give an example taken from Table VII., which demonstrates how before the power of the serum enters into the domain of constant results a large zone exists in which there are oscillations depending precisely on the aforesaid reasons. It results from the experiments reported in this table that, while a dose of serum 1 in 25,000 is undoubtedly sufficient to protect the rabbit against the established subdural infection, the smallest errors which enter into the determination of the same infection are not less compensated for completely by increasing the dose of serum twenty-five times (e g., Examples 142 and 143 with dose of mean ratio of 1 in 1000); but it is necessary to reach a dose 100 times higher (e.g., Examples 103, 104, 105, with a mean dose of 1 in 250) in order to see all the errors indicated and compensated for, and to save all the animals. We understand, therefore, that the data which ought to guide us in the determination of the power of a given serum should be considered in connexion with the special conditions of the infection of rabies. We were not able, therefore, to construct our scale upon experiments on one or a few animals and with the minimum dose of serum as we do for an intoxication exactly measurable by dose; but it was necessary for us to make for each serum a longer series of experiments with diverse quantities and so find some dose which would in all the series give positive results. We have ordinarily made for every weight three series of experiments, each composed of from two to five animals, trying for the canine virus the powers 1 in 25,000, 1 in 1000, and 1 in 250; for the fixed virus in the majority of cases we have tried the powers of 1 in 400, 1 in 200, and 1 in 100. The first series in which all the animals survived established the "title" of the serum under examination.

TABLE X.

Number of register.	Weight of rabbit in kilog.	Quantity of serum injected under the skin twenty-four hours before infection.		Infecting units of canine virus under the dura mater.	Result of experiments.
		Absolute.	Relative.		
103	1·320	5 c.cm.	1 : 264	One	Lived.
104	1·380		1 : 276		Lived.
105	1·190		1 : 238		Lived.
142	2·500	2 c.cm.	1 : 1250	One	Lived.
143	1·970		1 : 985		Died 22nd day.
138	1·770	0·07 c.cm.	1 : 25000	One	
139	1·680		1 : 25000		Died 10th day.

Thus, in this instance the title where the virus of rabies "da strada" is used is 1 in 250, which is rather low because the blood was taken prematurely—that is, the tenth day after vaccination. With this method of standardising some of our figures naturally may be too high to express the power of our serum, because, putting aside losses which occur to the serum in the body, as we shall demonstrate later, there is, on the one hand, required a constant result; whilst, on the other hand, the dose of the virus chosen by us for infection does not actually represent the minimum fatal one. Hence the title of the serum which by our method is established is in effect only a multiple of the least dose capable of acting against the least infection adopted. With the actual methods of vaccination we were able to obtain a serum of a power sufficient for the needs of practice, which we have taken as the unit of measurement—a species of normal serum analogous to that of Behring for diphtheria—which we shall call "typical serum"= ST. Our typical serum has the following activity. It is employed subcutaneously as a preventive twenty-four hours before the infection made with the infecting unit of the canine virus introduced under the dura mater, and is effective in the case of the rabbit in a dose 1 in 25,000—that is to say, with about

Digitized by Google

a drop and a half of serum we protect an animal weighing 2 kilogrammes. As a curative against the same virus, introduced into the sheath of the sciatic nerve diluted to twice the strength used for the subdural infection, our ST injected under the skin at the eighth day—that is, towards the middle of the period of incubation—is of value in cutting short the disease in the dose of 1 c.cm. for a rabbit, say, of two kilogrammes. Against the fixed virus by subdural infection made with one infecting unit our ST is effective at the "title" of 1 in 100—that is to say, at the dose of 10 c.cm. per kilogramme of the animal injected under the skin twenty-four hours before infection. By direct contact *in vitro* 1 c.cm. of our ST neutralises a quantity of fixed virus corresponding to 1200 infecting units; this determination *in vitro* against the fixed virus is therefore the method which we hold is the most suitable and which we commonly practise in order to standardise a given serum. Hence we shall base upon it our "protective unit," and we shall call by that name the quantity of serum capable of neutralising directly the action of an infecting unit of fixed virus. The figures set forth above, we repeat, are established by constant results, whilst even for the smaller doses, the half or the third, the positive results are always sufficiently numerous. There exists a constant relation between the various ways of establishing the power of the serum, whence it is possible, the serum being proved with one unit of virus, to deduce the dose which will be suitable for the others. The preventive dose against the canine virus is curative on the eighth day as 1 in 10; the preventive against the virus of rabies is to the preventive against the fixed virus as 1 to 200, and so forth. In like manner, if we have a serum differing from the typical serum—for example, 10 times less active $\left(\frac{ST}{10}\right)$—it will be enough to multiply or divide all the ratios by the highest power or the lowest power discovered experimentally by any of the methods of standardisation.

2.—EXAMPLES WHICH DEMONSTRATE THE IMPORTANCE OF EXACT DOSAGE OF THE VIRUS AND OF THE SERUM.

In order to give exactly the reason of the importance of the facts set forth, and to demonstrate the constant necessity of establishing a safe line of practice with which we are able in every case, without exception, to arrive with precision at the power of a given serum, we report a series of experiments in which the influence of an imperfect dose appears to be manifest. The category A of the experiment in Table XI. demonstrates how even only a fraction of the full dose of the canine virus injected is enough to kill the animal with little delay. In category B we see that against the usual injection with the fixed virus the serum is effective at 1 in 108 (Example 173); at 1 in 118 death follows with noteworthy delay (Example 163); on the other hand, with a proportion of serum considerably greater—viz., 1 in 77 (Example 158)—death comes without delay through a double infection being made. In category C we see that the serum is active at 1 in 25,000 as long as the infection is made with the infecting unit, using the dilution 1 in 50 of the canine virus. When, therefore, the infection is made with the dilution 1 in 20, which is more than twice as much concentrated, death follows without delay (Example 19); if, however, we raise the proportion of the serum as much as

TABLE XI.

Conditions of experiment.	Number of register.	Weight of rabbit in kilogrammes.	Infecting units.	Quantity of serum injected preventitively under the skin. Absolute.	Quantity of serum injected preventitively under the skin. Relative.	Results.	Observations.
A. Excess of virus "da strada."	89	1·390	1	c.cm. 5	1 : 278	Lived.	(1) Two trepannings were made through a reflux having been had from the first.
	99	1·370	1½	—	1 : 274	Died 28th day (1)	
	100	1·430	1	—	1 : 286	Lived.*	
B. Excess of fixed virus.	158	1·390	2	c.cm. 18	1 : 77	Died 8th day (1)	(1) Receives two complete infections with a day's interval.
	163	2·360	1	,, 20	1 : 118	Died 44th day	
	173	1·620	1	,, 15	1 : 286	Lived.	
C. Disproportion between the dose of serum and the power of the infection with the canine virus.	35	1·560	½	c.cm. 0062	1 : 25,000	Lived.	(1) Infection with 2½ infecting units succeeds only when we increase correspondingly the quantity of serum, making it 2½ times greater. Ex. 18.

that of the virus is raised, the animal survives. It is clear that if we have even a slight over-dose of the virus the action of the injected serum becomes completely masked, since the animal so treated dies; it will thus appear, as it did to us and as it has without doubt appeared to other observers, that a good protective serum has been obtained without the fact being recognised. A substantial difference has been noted between the immunity conferred by the injection of a virulent material more or less attenuated—i.e., vaccine—and the immunity conferred by the injection of serum. This last immunity soon establishes itself, but in compensation lasts only for a much more limited time than the first. This fact enters little into consideration in the case of infections which have a rapid course and which have not the faculty of remaining long latent in the organism. Rabies, from this point of view, exists under the most favourable conditions, since it can develop many months after the actual contagion takes place. It was absolutely necessary to establish whether by means of antirabic serum the malady could be for ever banished, or at any rate kept in abeyance within the time during which the immunity conferred by the serum would last. To this end we have never judged any result as being definite unless the animal has been kept under observation for a period of not less than four and even up to six months. By this system of observation we have been able to convince ourselves that when the serum is administered in sufficient quantity, in proportion to the degree of infection, the danger of a remote manifestation of rabies is completely eliminated. It is very true that some animals treated with serum have died at a period still further removed from the time of infection, but that has happened solely when the proportion between the dose of the virus and that of the injected serum was found to be incorrect. In proof of this we have consulted the entire series of our "protocols" to see what animals would have died after considerable delay, and we have gathered them all into Table XII., putting before each of them the reasons of the partial failure. There are only nine animals among a total of 300; to these we may add those treated with serum against the infection with canine virus and with the fixed virus after having found more exact methods of fixing the dose. Thus, in the earlier years, when we possessed weaker serum and did not fix the dose — either the concentration or the quantity of the virus—only exceptionally have we seen death follow at a time remote from the infection. The table demonstrates that the delay follows more frequently between a month and a half and two months after the infection and never passes beyond the third month, whence the duration of observation practised upon our animals must be held to be sufficient for the formation of a definite judgment. It is noteworthy that the animals which have presented delay in death all belong, except one, to those treated with the serum of a sheep to which was applied an unsuitable system of vaccination—it may be by excess of the dose, it may be by incomplete digestion, which we have discussed at the beginning of this article. There is, however, one animal infected with the fixed virus which has presented considerable delay in its death. It is the only one out of a hundred rabbits infected with the fixed virus and treated with our serum. This rarity is in harmony with what we previously enunciated—that is, that either the fixed virus becomes completely neutralised by the serum or that the quantities which remain, however small, are the remains of a virus so energetic that they are capable of producing death very rapidly. Example 163 does not invalidate the law, because in this case the quantity of serum injected very nearly approaches the fixed dose, so that the quantity of the fixed virus not neutralised must have become extremely small, whence the length of time demanded to produce death. And then, by this table, we are able to substantiate once again the fundamental law of serum-treatment in rabies—viz., that the virus and the serum act reciprocally to the determined dose, and that a disproportion between them leaves active a part of the virus, which produces effects as much more remote as the quantity left was smaller. With regard to the *duration of the immunity*, we are not at present able to pronounce absolutely; but from the preliminary experiments, which form part of a series of special researches upon this point and to which we shall refer specially at some future time, we are already able to infer that the strength of the immunity conferred on the rabbit, by the serum injected after the infection with the virus as well as with the serum only, is of a sufficiently long duration. For the rest, when it is demonstrated that the mechanism with which the serum acts is that of destroying the virus, and that the serum injected can become sufficient in quantity and strength to make this distinction complete by eliminating absolutely any later development of the malady, the duration of the immunity assumes a secondary importance from our point of view.

(To be continued.)

ROUGH NOTES ON REMEDIES.[1]

By WILLIAM MURRAY, M.D. DURH., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE NEWCASTLE-ON-TYNE HOSPITAL FOR SICK CHILDREN, AND LATE LECTURER ON PHYSIOLOGY AT THE UNIVERSITY OF DURHAM.

No. III.

NITRATE OF SILVER IN EPILEPSY.

I HAVE read with great interest the Manchester address and the clinical lecture on "Silver and Epilepsy" by Dr. Gowers. The former is a marvellously lucid exposition of what can at present be known of the intimate physics of life, and it penetrates further into the "mist on the horizon" than anything hitherto produced. I trust Dr. Gowers will give us another insight into the workings of his mind on this subject. If I have grasped his meaning aright, he thinks with reason that while ordinary muscular contraction is (like the heat given off in ordinary combustion) due to the force set free by the union of carbon and oxygen, which in combining have parted with some portion of their minute motion, and therefore move less rapidly when combined, the amount of energy given off is the difference between the minute motion of the compound and the minute motion of the elementary atoms. He thinks that while the burning of fuel such as coal is comparable to the ordinary contraction of muscle, the violent explosion of more highly combustible matter is comparable to the violent muscular explosion of an epileptic fit. With regard, then, to the treatment of epilepsy, it is manifest that our efforts must be directed to the removal or hindrance of this tendency to an explosive discharge in the nervous and muscular systems. Without attempting to explain how this inhibited state of the nerve centres is brought about by several remedies whose effects are fully established by abundant experience, I think I am justified in saying that some of them at any rate do their work by hindering this explosive union of atoms or molecules. One of these remedies—nitrate of silver—offers a fair field for study in this direction. I have often expressed the opinion years ago that a deposit of silver in some form, probably chloride, in the molecules or submolecules of the nerve cell and fibres so altered the polarity—i.e., the explosive tendency—of the molecules as to arrest the epileptic discharge. And now comes the more accurate and more complete interpretation of Dr. Gowers, who gives us a mental picture of what actually takes place in the action of the nervous and muscular tissues when force (minute motion) is set free. He points out that the susceptibility to nervous and muscular action needs but the influence of a stimulus—i.e., of "added motion"—to bring about a manifestation of the latent energy in these tissues, and that an increase of susceptibility or of stimulus—i.e., added motion—may evoke an epileptic explosion. It seems to me a fair inference to suppose that a remedy which is deposited in the tissues—perhaps irrevocably deposited—may by its chemical inertia interfere by its presence with the minute motion or chemical activity of adjacent atoms and thus prevent their explosive union. The solution of this question would be materially aided by an inquiry into the nature of the silver deposits. Do they exist permanently in the interior of the body as they do in the exposed parts? They doubtless do exist in some of the mucous membranes—in the mouth, for instance. Are there any changes of colour in the nerve tissues indicating an oxide of silver there? A microscopic, or chemical, or perhaps a spectroscopic, examination would help us to decide this question of silver deposit. As I know of no ascertained facts I am obliged to fall back on the old-fashioned empirical

[1] Nos. I. and II. of this series were published in THE LANCET of Feb. 25th and Nov. 4th, 1893, respectively.

Digitized by Google

resource[2]—experience. What does experience teach us as to the use of nitrate of silver in epilepsy? Experience has taught us two remarkable things—first, that nitrate of silver will cure epilepsy where the bromides have utterly failed; and, secondly, that a patient who has subjected himself or herself to a course of silver, producing a deposit, secures a remarkable immunity from a number of small nervous ailments, such as neuralgia, gastric uneasiness with nervousness, &c. I think this latter effect throws a flood of light on the subject and corroborates the view that "the silver blunts the polarity of the nerve centres," renders them stable and less easily disturbed by outward influences, which would come under the head of Dr. Gowers's "added motion." In confirmation of these statements I must produce some "facts," or my theory will fall to the ground.

I submit the following case, which is one of several, in proof of the power of nitrate of silver to cure epilepsy. Twenty years ago I was consulted by the manager of an important railway department. He had become a confirmed epileptic, suffering from frequent and severe fits. Bromides had been fully tried in large doses by several eminent physicians. Partial relief only was obtained, and that at a great sacrifice of memory and general business alertness (I sometimes wonder whether the mere postponement of fits is worth the serious detriment which the patient suffers in these respects from bromides), and the gentleman was face to face with the resignation of a valuable appointment. I plainly put before him the alternative—Did he mind the leaden tint which would certainly follow a long course of silver if he got rid of his fits? "Not a bit," said he, "it is a mere featherweight in the balance compared with my present heavy burden." So I put him on nitrate of silver for nine months. He had no fit after the first month of the course, and he has never had one since. His health has been much better—no small ailments—and he bears me no grudge. I passed him the other day, and he, as he always does, lifted his hat with a grateful smile. This is in severe contrast with Dr. Gowers's patient, who jacketed his medical attendant, but then, poor fellow, he was not cured.

Now, again, a gentleman in easy circumstances has been more or less epileptic for thirty years; he has been a prey to a number of small ailments, to which, I believe, bromide by lowering vitality largely conduces. Neuralgic headaches, muscular twitching, lassitude, frequent lapses of *petit mal*, not to speak of loss of memory and an occasional large fit, combined to render his life a burden. He deliberately accepted a course of nitrate of silver, regardless of consequences, and has since reaped his reward. He is seldom out of sorts, is comparatively free from headaches, has no twitchings, and has never had a trace of epilepsy, not even *petit mal*. I might refer to several similar cases. The above sufficiently illustrate my views. I ought to state that in this latter case the faintest touch of leaden hue was produced, and the patient was not aware of it.

With regard to the effect of nitrate of silver in minor ailments, there is no more striking illustration of it than in those cases of weak, irritable stomachs which are characterised by intense depression of spirits, apprehensions, and failure of pluck or courage. In these cases a remarkable change takes place both in the functions of the stomach and in the tone of the nerve centres of emotion. I will refer the readers of THE LANCET to an old work, "Johnson on Indigestion," which contains many illustrations of these effects of nitrate of silver. To get the best results in these "stomach cases" the nitrate should be dissolved in distilled water and taken on an empty stomach. I think one gets a distinct local effect on the mucous membrane as well as the more remote effects on the nerve centres by giving it in this form.

I fear my rough notes will stand out in rude contrast when placed beside the refined disquisition of Dr. Gowers, but this result I may claim—that I have given a practical application of his theory, and to some extent may have confirmed his speculative views.

Newcastle-on-Tyne.

[2] A post-mortem report of a patient stained with nitrate of silver is very desirable. Does it exist?

MEDICAL MAGISTRATES.—Mr. John Wm. Rowlands, L.R.C.P. Edin., L.F.P.S. Glasg., of Llanaelhaiarn, has been placed on the Commission of the Peace for the county of Carnarvon; and Mr. John M. Dennis, L.D.S., of Grimsby, has been appointed a magistrate for that borough.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

NOTES ON A PECULIAR CASE OF PUERPERAL SEPTICÆMIA.

By CHARLES H. GEOFFREY RAMSBOTTOM, M.B., B.CH.VICT.,
LATE SENIOR RESIDENT MEDICAL OFFICER TO ST. MARY'S HOSPITAL AND TO THE MANCHESTER AND SALFORD LYING-IN-HOSPITAL.

I SHOULD like to mention a case of puerperal fever, which appears to me to have been one of pure septicæmia—that is to say, a case where the blood was a form of reservoir of toxic organisms without any absolute local manifestation whatever. The patient had been attended by a midwife, who, as no progress seemed to be made, and as, to use her own expression, she could not feel any child presenting, sent for my assistance, stating that the woman was flooding. On my arrival I found a marginal placenta prævia and delivered easily with forceps, expressed the placenta and attended to the usual antiseptic and aseptic precautions. The patient progressed favourably until the third day, when she had a rigor (102·5° F.). I washed out the uterus with a 1 in 2000 solution of perchloride of mercury and gave her quinine. The next day she seemed all right. There was nothing retained in utero. The following day, however, she had another rigor (103°). I repeated the previous treatment, and on the next morning the temperature had fallen to 101°, when I again washed out the uterine cavity with perchloride solution; but in the evening the temperature again rose to 103°. I then ordered quinine regularly, douched her myself twice daily, and prescribed milk, meat juice, eggs, and stimulants for diet. I noticed her right leg was swelling, and consequently this was wrapped in cotton wool (fifth day from her delivery). The following morning the temperature was 103° and rose to 104° in the evening, the pulse being 130. The temperature ranged from 103° to 105° from Oct. 22nd to Nov. 16th (twenty-four days), and was oftener at 104° than otherwise during this long period; on one occasion the temperature was 106° and on another 106·5°. The pulse varied with the temperature, from 110 to 130 per minute, and yet throughout all this period her respirations were seldom exaggerated. The tongue was moist and consequently she took large quantities of fluid nourishment, stimulants, and quinine, until she became quite deaf. She never became delirious, never complained of pain, except a little headache in the evening and also when her temperature became hyperpyretic, on which occasions she complained of feeling a great oppression in the chest and expressed the belief that she was dying. During the whole time she perspired profusely, and although she had cold packs, quinine, salicylate of soda, antifebrin, Dover's powder, uterine douches of perchloride of mercury, carbolic, and uterine insufflations of iodoform, no definite impression could be made on the febrile condition. On Nov. 17th, a calendar month from the date of her delivery, her temperature became 102°, and on the following morning 101·5°, and then on the same evening it rose again to 103°, and she developed a cough with expectoration; she complained of pains, the first she had noticed during the long illness, in her chest, and began to expectorate a frothy rusty sputum, and on auscultation I detected fine râles and roughened breath sounds, but no definite dulness. She rapidly became worse and died, exhibiting the Cheyne-Stokes respiration.

The interesting features of this case appear to me to be that the onset was severe and almost from the first the blood seemed to become toxic, and that there seemed to be a struggle between micro-organisms and the human organism, whether lymph cells or otherwise, for supremacy; moreover the reason of the high temperature for so long a period and the comparative ease of the patient and the readiness for imbibition of nutriment may be accounted for a little, perhaps, by the free action of the skin and her fixed determination to get better, as throughout she struggled bravely to recover. Another curious point is that from the leg beginning to swell—it was exactly like a condition of

Digitized by Google

phlegmasia dolens—she had no pain in it whatever. On the whole it was, in my opinion, a rather remarkable case of puerperal septicæmia.

Granby Fields, Queensbury, Bradford, Yorks.

COMPLETE TRANSVERSE FRACTURE OF THE HUMERUS BY MUSCULAR ACTION.

By GEORGE T. WILKINSON, L.R.C.P. EDIN., L.R.C.S. IREL.

A CASE of the above kind is, I think, of sufficient rarity and interest to merit reporting. On Aug. 3rd last a youth aged sixteen years, one of twins, but differing from his brother in being much taller and more robust and muscular, in fact, being a youth possessing physical development above the average, was brought to my surgery complaining of pain in, and inability to move, his right arm. On examination I found a complete transverse fracture of the humerus below the insertion of the deltoid. He informed me that being sent to turn in a horse which was out on grass he threw a stone at the animal, and after the missile had left his hand he felt a sudden severe pain and lost all power in his arm. The fracture united well and rapidly.

Cloughton, Scarborough.

SPONTANEOUS ANEURYSM OF THE BRACHIAL ARTERY SUCCESSFULLY TREATED BY PROXIMAL LIGATURE.

By FREDERICK PAGE, M.D. EDIN.

A MAN aged thirty-one years, with very extensive aortic disease, showed me in August, 1894, an aneurysm of the brachial artery about the size of a hen's egg at the bend of the left elbow. It arose without any injury, and had been noticed only for a few weeks. It was increasing in size, and causing so much pain that the arm was useless to him. Twelve years ago, wishing to enter a benefit society, he was rejected on account of heart disease. A year after this he contracted a venereal sore on the penis, but no constitutional symptoms followed, and he was not treated for syphilis. The artery was tied a little above the joint with a catgut ligature. No difficulty arose from the chloroform. The wound healed by first intention. Now, a year after operation, there is no trace of the aneurysm, and the patient says his left is the better arm. Spontaneous aneurysm of the brachial artery is rare and not always successfully treated by proximal ligature. For these reasons I think the case is worth recording.

Newcastle-upon-Tyne.

CASE OF ORBITAL SARCOMA IN A CHILD.

By W. M. BEAUMONT, M.R.C.S. ENG.

A GIRL aged ten years came to the Bath Eye Infirmary on Sept. 17th, 1893, complaining of a red, hard, new growth of one month's duration in the ocular conjunctiva. It was situated at the inner commissure of the right eye and had the appearance of a small cock's-comb, which showed between the lids when they were closed. It was apparently quite superficial and was easily removed. Under the microscope it had the structure of a simple polypus, small bloodvessels and cells lying in a matrix of connective tissue, and it was not pigmented. It was considered innocent and the patient returned home. She came back six months later (April 2nd, 1894) with a large recurrence in the same situation, but involving the upper lid. Chloroform was administered, and the growth, together with the inner half of the tarsal cartilage, excised; the globe was quite free and the conjunctiva and orbital cellular tissue were alone affected. On examination the tumour was found to be soft and friable, and under the microscope its structure was highly suspicious of malignancy. The wound, however, healed satisfactorily, and she had no pain. She returned home again well, but the distance from Bath prevented the possibility of watching her constantly. On June 3rd she came back again with a recurrence, which filled the orbit and proptosed the eye. There was still no pain, and the eye, though immovably fixed, was not involved in the growth. Chloroform was administered and the eye removed; the orbit was exenterated, the whole of the cellular tissue being infiltrated with the soft neoplasm as far back as the sphenoidal fissure. The tumour was about three times the size of the globe, but there was not much loss of blood in removing it. If there had been any doubt from the clinical symptoms the microscope now clearly showed the characteristics of a round-celled sarcoma. Gradually the growth reappeared until there was a tumour as big as her fist outside the patient's orbit; it then became stationary and began to slough. She died exhausted, but without having suffered much pain, on Sept. 23rd, 1894. It is not always that one is able, as in this case, to watch the life-history of tumours from their innocent infancy to their malignant maturity. It has long been recognised that growths may remain quiescent for long periods and then, volcano-like, burst suddenly into fury without any explainable reason. In the case described above it would seem almost as though the operation were the cause of the change in the character of the tumour, and that by it a fatal traumatic malignancy was started.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Procemium.

KENSINGTON INFIRMARY.

A CASE OF CONGENITAL ABSENCE OF THE RECTUM; NECROPSY.

(Under the care of Mr. W. M. WOODHOUSE, Senior Assistant Medical Officer.)

FROM time to time reports of cases of imperforate anus and partial development of the rectum have appeared in the medical journals, but a considerable period has elapsed since a case of complete absence of the rectum has been recorded. It is also noteworthy that in this instance the malformation escaped notice for three days. The exact condition here described cannot usually be recognised until an incision has been made at the site of the anus in the hope of reaching the bowel. The type of pelvis found at the post-mortem examination is that which is commonly seen when the rectum is absent. The following are the details of the case.

A woman aged thirty years was admitted into the Kensington Infirmary three days after the birth of her first child—a male. The mother, a thin, weakly looking woman with a bad family history of phthisis, stated that her child had been constantly sick since six hours after birth, when she first nursed him, and although abundant urine had been passed the bowels had never acted. A purgative powder, obtained from a local druggist, had been administered without effect. On examination shortly after admission Mr. Woodhouse found that the child was thin and puny, repeatedly crying out and exhibiting evident symptoms of pain. The abdomen was much distended and tympanitic. The anus was absent, nor was there any evidence of its presence in the normal situation beyond a slight depression close to the median raphé. There was no impulse or bulging in the perineum when the child cried. It was decided to at once make an attempt to relieve the child and establish patency of the rectum, which it was thought would probably be within a short distance of the surface. The patient having been placed under chloroform, Mr. Woodhouse made an incision an inch long in the middle line in the normal situation of the anus, cutting upwards and backwards, and keeping close to the sacrum. From time to time the little finger was introduced into the wound, but nothing indicating gut could be felt, even at the depth of an inch and three-quarters. He then proposed to perform inguinal colotomy, but the anæsthetist considered it inadvisable to continue the chloroform owing to the exhausted

Digitized by Google

condition of the patient. The wound was then dressed with boracic acid powder and salicylic wool. The patient gradually became weaker and succumbed five hours after the operation. The post-mortem examination revealed the fact that the intestines were much distended, but otherwise normal, until a point was reached close to the brim of the pelvis in the left iliac fossa, when the sigmoid flexure abruptly terminated in a cul-de-sac. The peritoneum was intact and showed no signs of peritonitis. All the other pelvic organs were normal. The pelvis itself was smaller than usual and the tuberosities of the ischium much closer together.

Remark.—No similar case has occurred in nearly 2000 births in this infirmary, and only one case of imperforate anus is recorded.

ROCHDALE INFIRMARY.

A CASE OF HYDROPHOBIA.

(Under the care of Mr. R. B. SELLERS.)

IT is, we think, important to publish from time to time the account of a case of hydrophobia, if only to remind members of the profession of the symptoms of the disease and its hopeless nature when it has developed. Rabies in dogs in this country is by no means stamped out; in fact, during last year there was a very considerable increase in the number of animals affected. During the six years 1889–1894 the numbers were 312, 129, 79, 38, 93, and 248 respectively. The preventive treatment of Pasteur is at present the only one in which any reliance can be placed; and although it may be commenced any time after the bite before the symptoms develop the patient's chances are much improved if it is carried out early. We have not space to enter into the statistics of patients treated by this method; thousands have now been submitted to it; but we would remind our readers that, instead of a mortality of 15 per cent., which follows the bites of animals supposed to have been rabid, under any other method of treatment, Pasteur's plan of preventive inoculation has reduced the mortality to 0·92 per cent., and this amongst patients bitten by animals certified to have been rabid. For the notes of this case we are indebted to Mr. W. E. Davies, resident medical officer of the Infirmary.

On Monday, Sept. 2nd last, at 10.15 P.M., a youth aged seventeen was admitted to the Rochdale Infirmary suffering from hydrophobia, to which he succumbed on Tuesday, Sept. 3rd, at 3.40 P.M. From evidence given at the inquest it appears that the patient was bitten by dogs on two different occasions. The first bite was inflicted on his leg at some indefinite date more than twelve months ago. The second bite was inflicted on May 3rd of this year. On the latter occasion he was bitten on the proximal phalanx of the middle finger of his right hand. The hand was put into a strong solution of salt and hot water, but not cauterised until two hours and a half later, when he was attended to by Mr. Lord of Castleton. The dog was destroyed on the same day, having bitten another man just before it was poisoned. It was not believed to be rabid, but was done away with in order to prevent it from biting children. No bad symptoms set in until Sept. 2nd. The boy complained occasionally of stiffness and pain in his right arm, these being attributed to playing cricket. From the evidence given he did not seem to trouble about the bite after the wound healed. On Monday, Sept. 2nd, he went to wash himself during the afternoon and appeared to be suddenly seized with a kind of spasm, jumped back from the water at once, and walked into the house. He made no remark, and no further notice was taken until he sat down to tea at 5 P.M. He then had great difficulty in taking any liquid and could only take sips. He was advised to see a medical man and went to Mr. Lord, who ordered him to bed and then arranged to bring him to the infirmary. On admission Mr. Lord gave a brief history of the bite, and the patient was not questioned. Mr. Lord refrained from mentioning his fears to the boy and from questioning him about the dog-bite, but telegraphed for the parents. No signs of inflammation were noticed about the finger, and the patient made no complaints about it. The youth, who was tall, thin, pale, and with an anxious expression, complained of attacks of spasm, with difficulty in breathing, whenever he attempted to take a drink. On being offered a little milk in a cup he took the cup to make an effort, and then shrank away from it with horror and begged not to be forced to take it. He offered to take a little from a feather, as he was very thirsty. When asked why he would not drink he explained that attempts at drinking brought on attacks of spasm with difficult breathing. He was placed in an isolation ward, and half a grain of morphia was injected subcutaneously into his arm. He had a very restless night, no sleep, complained of great thirst, and took drops of water from a camel-hair brush, making sharp efforts each time he took a drop. Even these drops brought on a spasm in his throat occasionally. All the muscles of the neck were then hard. He made several attempts to get up and asked for his clothes in the early morning, said he was going to Paris and talked wildly of dog-bites, although all care had been taken not to mention such things in his hearing. During the night he had periods during which he was maniacal. At 8.30 A.M. on Sept. 3rd he became furious and jumped on one of the nurses when she happened to turn her back for a minute, but did not do her any injury beyond pinching her severely. A strait-waistcoat was then put on, and half a grain of morphia repeated. He took a great dislike to the nurse above mentioned, but allowed the night nurse to go near him and give him water by means of the brush. He bid others keep away and said that though he had no wish to hurt anyone he could not help himself if they came near. At 10 A.M. Dr. March, Mr. Pooley, and Mr. Sellers, three of the honorary surgeons, saw the patient, held a consultation, and agreed with the diagnosis made. At this time the muscles of the neck were rigid, both sterno-mastoids being prominent. His appearance was wild and he talked incessantly, though there were intervals during which he was less excited. A handkerchief was waved casually in front of him, but he objected and gasped for breath. He begged for the proceeding not to be repeated. He still talked of Paris. He recognised one of the surgeons, to whom he delivered a telegram at some period, and knew one person from another quite well. His room was kept dark and everything as quiet as he himself would permit. His temperature was 103° F. and the pulse 120. At the consultation Mr. Sellers suggested subcutaneous injections of conia. Accordingly it was decided to push the conia until its physiological action was produced, the object being to paralyse the muscles. Three minims of a solution of conia with rectified spirit and water (strength 1 in 6) were injected hypodermically at 10.15 A.M., 11 A.M., 12 noon, and 1 P.M., and four minims at 2 P.M., but no effect appeared to be produced. The temperature at 1 P.M. was 103·4°. During this time he continued his excited conversation about dogs and Paris, had illusions, said he could see his pet dog through the door, and begged that it might be allowed to come in so that he could kiss it. He had no sleep, but the spasms were few. The muscles of the neck continued rigid, but not always of the same tension. At 2.30 P.M. he again became very boisterous, kicked all the clothes off, and tried to kick the attendants. He expectorated a great deal of frothy mucus all over the room and at his attendants. His lower limbs had to be fastened to the bed to keep him in. His pulse was rapid and weak. One-third of a grain of morphia was injected hypodermically. At 3 P.M. he became quiet, and mucus collected in his throat. An attempt to remove this brought on a spasm, and the patient gasped for breath. He gradually passed into a state of coma and died at 3.40 P.M. from exhaustion and asphyxia.

Remark by Mr. SELLERS.—I cannot but regret that the conia was not at hand when the boy was admitted.

THE Medico-Psychological Association of Great Britain and Ireland announce that the next examination for their certificate in nursing and attending on the insane will be held on Nov. 4th, and that Monday, Oct. 7th, will be the last day for the entry of candidates' names. The Registrar (Dr. Spence, Burntwood Asylum, near Lichfield) will supply schedules, which should be filled up, signed, and returned to him at least four weeks before the date of examination.

TORQUAY MEDICAL SOCIETY.—On Friday, Oct. 4th, at 5 P.M., Mr. Hutchinson, F.R.S., will deliver an address to the above society on Heredity in Disease, in the Clarence and Avondale Institute (adjoining the Albert Hall). Members of the profession outside the Torquay district will be welcome on giving notice beforehand to Mr. G. Young Eales (honorary secretary), 7, Portland-place, Torquay, of their intention to be present. The annual dinner will be held in the Albert Hall after the meeting.

Reviews and Notices of Books.

The Climates and Baths of Great Britain. Being the Report of a Committee of the Royal Medical and Chirurgical Society of London. W. M. ORD, M.D. Lond., Chairman; A. E. GARROD, M.D. Oxon., Hon. Secretary. Vol. I., The Climates of the South of England and the Chief Medicinal Springs of Great Britain. London and New York: Macmillan and Co. 1895.

IT has, as everybody knows, become more and more the practice of persons under circumstances of health and disease—pleasure-seekers and health-seekers alike—to have recourse to the advantages, real and supposed, of change of climate. There is no subject on which members of the medical profession have more frequently to originate a recommendation in this respect, or about which they are more often appealed to by their patients for advice and suggestions. The amount of information of a more or less reliable—and sometimes, if the truth be spoken, of a very little reliable—character, that is scattered throughout various guide-books, pamphlets, and publications is no doubt considerable, but it is not always readily accessible, and when obtained, it may be added, is very often not of the kind that is required. It is not the precise, systematised, scientific information which is needed, nor are all the necessary data given on which to form a correct judgment as to the relative merits of different places so as to guide us in the selection of one of them as specially or best adapted for the purpose in hand. The Council of the Royal Medical and Chirurgical Society initiated, therefore, a really useful and important movement when in 1889 it resolved that "a scientific committee be appointed for the purpose of investigating questions of importance in reference to the climatology and balneology of Great Britain and Ireland, and to report thereon to the Council from time to time." The outcome of the labours of the committee in this direction, so far as they have at present gone, is the admirable volume now published. We do not think that we could do better than recapitulate some of the facts recorded in the preface as to the constitution of the committee and the nature and scope of their investigations, for they afford a guarantee of the recognised ability of the writers to conduct an inquiry of this nature and of the systematic and scientific methods on which they have tried to carry it out. As at first constituted the committee consisted of Dr. Ord (chairman), Dr. Ballard, Dr. Mitchell Bruce, Dr. Dickinson, Dr. Murrell, Dr. Frederick Taylor, Mr. Treves, Dr. Symes Thompson, and Dr. Herman Weber. Of these Dr. Ballard and Mr. Treves were unfortunately unable to serve. The following names were subsequently added to the committee: Dr. Ewart, Dr. Theodore Williams, Dr. Penrose, Dr. Norman Moore, Dr. Barnes, Dr. F. Roberts, Dr. Cheadle, Mr. Malcolm Morris, Dr. Maguire, Dr. Lazarus-Barlow, and Dr. A. E. Garrod, who was appointed to act as honorary secretary.

After instituting some inquiries of a general character the committee formulated letters to be addressed to medical men practising in the more important climatic resorts and bath-places, and prepared a form of inquiry for those connected with the smaller spas. In addition to the information obtained in this way certain members of the committee were deputed to make a personal investigation of the districts having important climatic value, and of the several bath-places. In both aspects, of course, a thorough appreciation and use of published and recognised meteorological reports was indispensable, and the investigators have for this purpose had recourse to the reports of the Meteorological Office and of the Royal Meteorological Society. Dr. Theodore Williams, a late President of the Royal Meteorological Society, was, it will be noted, a member of the committee. The present volume, which is the first report, gives the results of three lines of investigation—viz., the information received from medical men practising in the various localities, the results of the personal investigations to which we have referred, and the results of various statistical analyses of the several localities which were considered. In climatology are included the results of inquiry into the relative prevalence of health and disease and the influence of the climate on these in the several districts. The inquiries into climatology, so far, have mainly related to the south coast of England from the Land's End to the North Foreland.

The volume, which is an excellent and reliable handbook of reference, is not one that easily lends itself to the purposes of review as ordinarily understood, nor would extracts from it, if confined within any reasonable limits, afford any adequate idea of its nature and contents. We must be content, therefore, to give our readers in a more or less general way the impressions we have derived of its character and value, in addition to the information which we have summarised from the prefatory remarks to the volume itself. It contains, in the first place, a good map illustrative of the climates and baths of Great Britain, a coloured chart showing the annual death-rate per 100,000 persons in Brighton for twenty-two years, and numerous meteorological and statistical tables of a very useful kind are interspersed throughout the text.

We may briefly refer to some of the contributions to the volume and their authors. Dr. Ord is the writer of some excellent introductory remarks on the climates of the South Coast of England and on the medical springs of Great Britain, as well as of the reports—written in conjunction with Dr. Garrod in both cases—of the medicinal springs of Bath and Buxton. Dr. W. H. Dickinson treats of the climate of Cornwall, Dr. Symes Thompson and Dr. Lazarus-Barlow of that of Devonshire and the Channel Islands, Dr. Mitchell Bruce of Somerset, Dr. William Ewart of the South-Eastern Counties and Surrey, Mr. Malcolm Morris and Dr. Penrose of the springs of Harrogate and Strathpeffer, Dr. Garrod of Matlock, Bakewell and Stoney Middleton, Droitwich and Leamington, Dr. Robert Barnes of Woodhall Spa, Mr. Malcolm Morris of Moffat, and Dr. Frederick Roberts of the medicinal springs of Wales.

The line of treatment generally adopted by the contributors to the volume deals with such points as the following:—The general, physical, geological, and topographical characters and climatology of the county or district and the sea temperature; and then the characters of the several towns and districts are taken up and described separately with reference to the vital statistics and the prevailing diseases, and more especially with reference to the several classes of disease for the cure, treatment, or amelioration of which these are adapted. Regarding the climatology, the medical history, and the advantages which a locality offers, the data and observations are very pertinent as well as sufficiently exhaustive without being too redundant and consequently confusing. The information has been carefully analysed and condensed and has been arranged in such a way as to afford facility of reference, and—a great point in a work of this kind—the contents are well indexed. In reviewing this volume we have selected several districts and places more or less well known to us, and have been much gratified with the results of our study of the medical climatology and medical history which is given of them, and especially with the spirit of impartiality and discrimination with which the materials have been selected and commented upon. In addition to change of scene a certain class of invalids needs a restful contemplation of nature remote from "trippers," while others want only sunshine, invigorating air, and sea breezes, and nearly

Digitized by Google

all are benefited by escaping from the dirt and turmoil of towns and by being able to live in the open air. The volume is, in our opinion, an excellent book of a very useful and practical kind, which was much needed by the medical profession and for which they will be very thankful to the committee of the Royal Medical and Chirurgical Society of London. The task imposed upon them was a laborious one, and the members of the committee have fulfilled it with honesty and ability.

The Causes and Treatment of Lateral Curvature of the Spine. By RICHARD BARWELL, F.R.C.S.Eng., Consulting Surgeon to Charing-cross Hospital. Fifth Edition, revised. London: Macmillan and Co. 1895. Pp. 216. Price 6*s*.

THE treatment of lateral curvature of the spine has for many years been the subject of great divergence of opinion. There are some who look to mechanical support for a cure of this condition. Elaborate contrivances of bands, bars, straps, and springs attempt to "support" the patient's body and to force back the displaced bones into their normal position; yet, by depriving the muscles of all inducement to act, they lead to their further wasting and an increase of the feebleness and the curvature, which the machine was intended to correct. Though occasionally one still meets with a patient encumbered with one of these "supports," fortunately these methods are now but rarely used, as a more correct and scientific knowledge of the pathology has led to a wiser and more successful treatment. The wasted muscles are encouraged to take up once more the function, so long in abeyance, of supporting the spinal column, the relaxed ligaments are strengthened, and those which have become contracted owing to the malposition are gently stretched to their former length. At first, when the reaction commenced against the "mechanical" treatment, recourse was had to simple gymnastic exercises; but those then employed were found to be inadequate to remove the curvature already produced, though they were of value in strengthening the enfeebled muscles and in preventing further curvature. More systematic methods were developed later, and the results now attainable far surpass those formerly achieved; but the treatment must be carefully applied. We welcome, therefore, the reappearance, in what is almost a new form, of Mr. Barwell's work on Lateral Curvature of the Spine, as in it the important question of treatment is fully dealt with. The book contains an account of the various causes leading to lateral curvature, the diagnosis of the condition is amply gone into, and the author describes his "scoliometer"—an instrument by which smaller deviations from the normal can be detected than are recognisable without its aid. The chapters on treatment are satisfactory, and are illustrated by a number of engravings of patients showing the effect of the treatment; these have been prepared from photographs and illustrate well the deformity present. In an appendix are placed some chapters on the Anatomy and Pathology of the Spine. The whole volume may confidently be accepted as a careful treatise on a difficult subject.

The Climates of the Geological Past and their Relation to the Evolution of the Sun. By M. EUGÈNE DUBOIS. London: Swan Sonnenschein and Co. 1895. Price 3*s*. 6*d*.

THIS is a well-written little book on an interesting topic. It consists of a brief review of what is known of the climates of past ages according to palæontological and geological data, and also a series of arguments to prove that these changes have been due essentially to changes in the solar heat. The writer shows that while no fixed relation can be shown to exist between the climate and the character of the organic world—thus, identity of climate does not carry with it identity of vegetable and animal life, and *vice versâ*—yet the data of palæontology when cautiously interpreted are of great value in throwing light upon the climates of past times. These data are of the greater value the more recent the period whence they are obtained. The various climates of geology are passed in review. It is shown to be probable that there was a general greater equality of climatic condition in the past than now. Proofs are given that the fossil Arctic flora could only have originated in a warm climate. A mild climate is shown to have been a necessity for the coal flora. M. Dubois examines at length the well-known hypothesis that the differences between the climates of past geological ages and of the present time were due to a displacement of the poles. Very slight displacements of the poles are known to occur, but the author is entirely opposed to the view that such displacements are in any way adequate to produce the phenomena in question. We cannot reproduce his arguments, but we may quote the following passage: "Should astronomers and physicists raise no objections to a considerable displacement of the poles, the facts observed with regard to the Arctic vegetation of the Tertiary period still offer sufficient arguments against such a supposition. The displacement of the earth's axis and of the poles, if any have taken place at all in early periods, can have been but trifling, for the climatic distribution of organisms during those periods which we have been able to examine in this respect corresponds with zones which concentrically surround the present poles." The author proceeds to state the many cogent reasons which point to alterations in the solar heat as the efficient cause of the variations of climate in past geological ages. The book is well worth reading.

LIBRARY TABLE.

The Veterinarian.—The July and August number of the *Veterinarian* are both of considerable interest, not only to veterinary surgeons, but also to those interested indirectly in diseases of animals. A new feature in the July number is the use of photo mechanical blocks in illustration of various pathological and clinical cases; some of these illustrative blocks add greatly to the interest of the papers. The first paper is a "Case of Diseased Prostate in a Dog," by R. H. Clarke, M.A., M.B., M.R.C.S., and is well illustrated with naked-eye and microscopical specimens. Mr. Hutton records "The Great Outbreak of Anthrax in North Devon." The paper on Red-water Disease in Cattle is concluded, and suggested means of controlling the disease are given, the principle of which seems to be founded on the supposition that ticks are the carriers of infective material from animal to animal, and the author states that in his opinion the most satisfactory and effectual way of dealing with the ticks is to burn off the grass on the whole of the run, which would not only eliminate numbers of ticks, but destroy other parasites which spend part of their life history on the ground; protection from overheating from the direct rays of the sun is also recommended, whilst the carcases of cattle that die should wherever possible be destroyed by fire. A number of clinical cases are recorded, and a number of abstracted notes and science jottings make up a very readable number for July. In the August number is a paper on the Determination and Regulation of Sex in the Breeding of Horses, which is of interest to medical as well as to veterinary readers, as is also a paper on the Results of Tuberculin Test in a large Dairy Herd, from which out of 95 cows 71 were found to be tuberculous, 20 were sound, and 4 were doubtful, giving a percentage of 74 affected. It is interesting to note that of these 71 tuberculous cows most of the "suspects" were disposed of in the public markets, their future history being lost. It seems to be almost incredible that such disposal

Digitized by Google

should still be legal. The abstracts are again of considerable interest. The meetings of the various veterinary societies are reported in a separate supplement, as the new system has been found to work very well.

The Veterinary Journal and Annals of Comparative Pathology.—In the July number Professor Fraser's communication to the Royal Society of Edinburgh on the Rendering of Animals Immune against the Venom of the Cobra and other Serpents, and on the Antidotal Properties of the Blood Serum of the Immunised Animals is reprinted. An "Essay on Anæsthesia," by Mr. T. K. Mulcahy, is commenced in the July number and continued in the August number; whilst this is followed by a note on "The Early Days of Anæsthetics in Veterinary Surgery—a Retrospect," by Mr. E. Wallace Hoare. A number of clinical cases and cases in practice conclude the July number with the exception of the accounts of the various Veterinary Associations and a number of extracts and notes from foreign and other journals. In the August number the chief papers are one on Texas Fever by Principal Williams and an abstract of Professor Fraser's second paper entitled "Further Observations on Antivenene and on the Production of Immunity against Serpents' Venom; with an account of the antidotal properties of the blood-serum of venomous serpents." Cases in Practice, Legal News, Notes and Abstracts, make up a very interesting number.

The Elements of Botany. By FRANCIS DARWIN, M.A., M.B., F.R.S. (London: C. J. Clay and Sons and H. K. Lewis. 6*s.*)—This little volume contains the substance of the course of lectures on botany given to medical students at Cambridge, and is as far as possible meant to meet the requirements of the first examination for the M.B. degree at that University. The plan of the book is to teach general principles and illustrate them by suitable examples, those being chosen as far as possible which fit in with the object of the book. In this way, the general principles being learnt, the student can apply them to other examples which cannot be included in this work, and so further extend his knowledge. One of the most valuable parts of this work is the appendix, which gives directions for a course of practical work to illustrate the previous chapters. The book is well printed, easy to read, and the diagrams are clear; it should prove a valuable work for those commencing the subject.

A Handbook of Systematic Botany. By Dr. E. WARMING, with a revision of the Fungi by Dr. E. KNOBLAUCH. Translated and edited by M. C. POTTER, M.A., F.L.S. (London: Swan Sonnenschein and Co. New York: Macmillan and Co. 1895. 15*s.*)—This book is a translation taken partly from the text of the third Danish edition of Dr. Warming's work and also from Dr. Knoblauch's German edition of that work. It consists of a very complete systematic classification of plants with all their principal characteristics. The plan of the classification is arranged as far as possible according to the natural relations which the different orders bear to each other, and throughout the book these relationships are from time to time brought up by pointing out the links by which one order passes into another and by various comparisons, and so any disjointedness between the different sections is prevented. There is a short reference to the works of Hoffmeister and others, which serves to make clear the connexion between cryptogams and phanerogams. The fungi are classified according to the recent work of Brefeld and are divided into phycomycetes (algal fungi), mesomycetes, and myomycetes (higher fungi), each of these having their subdivisions and varieties. The bacteria have been revised by Dr. Migula, and those which are pathogenic to human beings are pointed out, with short references to the diseases which they may cause. There is an interesting appendix to the book in which many examples of artificial classification are given which have been formed by botanists at different periods, and that of Hooker and Bentham is very fully given. It is a book well worth reading and is well printed and illustrated.

Dod's Parliamentary Companion. Second Edition. London: Whittaker and Co., White Hart-street, E.C. 1895. Price 4*s.* 6*d.*—The election of a Parliament in which 188 new Members were returned makes us welcome the publication of the second edition for 1895 of this useful little book of reference. We do not think we can pay any better tribute to its value than by confessing that a glance at its pages has supplied certain items of knowledge with which we might, perhaps, have been supposed to be familar, but which have hitherto escaped us. We have always been puzzled as to the medical qualifications of the honourable Member for the Tullamore division of King's County (Dr. J. F. Fox), and in giving our list of medical M.P.'s had to acknowledge our inability to describe his qualifications. But Dod says he "took the degree of M.D. at the University of Cincinnati. Is an F.R.C.P. and S. of Kingston, Canada, and has practised medicine and surgery at Troy, New York State." We also find duly recorded the fact that the member for the Eastern Division of Norfolk (Mr. R. J. Price, whose name was omitted in our list) is an M.R.C.S., 1876, though he subsequently, like the present Solicitor-General, Sir R. B. Finlay, Q.C. (whose M.D.Edin., 1863, is also *en évidence*) became a barrister.

Herbal Simples. By W. T. FERNIE, M.D.Durh. Bristol: John Wright and Co. 1895. Price 5*s.*—We are told that the object of this book is to revive or retain the use of such simple herbs as are common amongst us and have been proved to be of medicinal value, and so it is recommended to the public in emergency and to the practitioner "when his customary medicines seem to be out of place or beyond reach." As an historical review of the use of many of these drugs the book is interesting and shows a large amount of knowledge and research on the part of the author; but much of it can scarcely be taken for serious use at the present day, for good as many of their actions may be we fail to see their superiority over those in use. The author believes largely in the law of similarity, which is carried to absurdity when in speaking of sundew he says: "The sundew when given experimentally to cats has been found to stud the lungs with true tubercular matter. ..... Meantime, it has been well demonstrated that at the onset of pulmonary consumption in the human subject a cure may nearly always be brought about, or the symptoms materially improved by giving the tincture of sundew throughout several weeks." We are also told that parsley, especially when uncooked, is liable to bring on epilepsy, but that it has been given with signal success in an inveterate case of that disease: indeed, the book abounds in such legends.

Wintering in Egypt. By ARTHUR J. M. BENTLEY, M.D. Edin., and Rev. C. G. GRINFFINHOOFE, M.A. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited. 1894.—This small handbook, which is very well illustrated with plates from photographs, is divided into two parts—one entitled "Under the Shadow of the Pyramids," the other "Hints to Invalids." It is popularly and pleasantly written, and gives a good deal of useful information of various kinds about a country which is full of interest, together with some helpful advice and hints to invalids and others as to their personal hygiene and the maintenance of their health in Egypt. The remarks as to the cases that are and that are not suitable for wintering in that country, the nature of its climate, and the dangers occasionally arising from chills, are sound and judicious. For the intelligent tourist and for suitably selected cases it goes without saying there is no more delightful or health-restoring place in the world than Egypt during the winter.

Bread, Bakehouses, and Bacteria. By F. J. WALDO, M.D. Cantab., medical officer of health to St. George's Hospital, Southwark, and to the Inner and Middle Temple; and DAVID WALSH, M.B., C.M. Edin. London: Baillière, Tindall, and Cox. 1895.—This volume is a reprint of five articles already published (one of them in THE LANCET, Oct. 20th, 1894), with the addition of reports of police-court proceedings against insanitary bakehouses, containing some very unpleasant details. The authors' experiments show that the heat required for baking does not invariably sterilise dough, as micro-organisms can often be cultivated from the centre of loaves within a few hours of their being taken from the oven.

Pocket Therapeutic Notes. Second Edition. Bristol: Ferris and Co. 1894.—This small volume of about 300 pages is a very useful and well-stored handbook of the more recent and energetic additions to the materia medica. Considering the number and variety of such preparations, there are few practitioners who do not find themselves occasionally in need of such a comprehensive book of reference as this. There is an appendix containing the fluid extracts of the United States Pharmacopœia and more than 160 formulæ of pills. Prices of the various drugs and preparations are appended.

MAGAZINES.

The September number of the *Practitioner* shows signs of the languor which pervades most periodical literature about this time of the year; still this magazine is never without one or two, at least, interesting pages. In an editorial note a suggestion is made that there ought to be a medical party in the House of Commons who would sink all political differences in order to "act together in safeguarding the public health." This is a most admirable suggestion, and one which we hope may soon assume reality. The Medico-Literary Causerie deals with Dr. Withington's "History of Medicine," which was recently reviewed in our columns. Mr. George Heaton has a good paper on the Symptoms and Treatment of Infective Disease of the Cerebral Sinuses, and there is a number of interesting notes from foreign journals.

The *Twentieth Century* for August has a thoughtful and suggestive article on Certain Bogus Insurances, condemning the anomalous system under which vendors of useless medicines and medical or surgical appliances are at full liberty to delude the public with mendacious advertisements. The law in this particular no doubt requires to be altered and amended with a view to the protection of the ignorant and unwary, for, as the writer of the paper remarks, sufferers may by such specious inducements be dissuaded from seeking proper advice during the initial period of disease, when professional skill has the best chance of giving relief. He might also have mentioned that the State is not free from complicity in the deception, for the Government stamp and the designation "patent medicine" no doubt encourage credulous purchasers in believing that advertised nostrums really possess the qualities claimed for them.

In the current number of the *Asclepiad* the principal articles are a memoir (with portrait) of John Abernethy and an essay on Cycling and Heart Disease. Sir Benjamin Ward Richardson continues the narrative of his researches in nervous matter and describes a new observation on the reproduction of forms by various electrified powders, of which bone-dust yields the best results.

A CORRESPONDENT having written to the Home Secretary calling his attention to the large number of deaths which have occurred in the past few months from lamp explosions has received the following answer:—"I am certainly favourable to the reappointment of a Select Committee on these dangerous oils and lamps, and hope it may be found practicable to start it again next session. Legislation, without the advice of the committee, is, I think, in this case well nigh impossible."

New Inventions.

THE AREMA VAPORISER.

THE treatment of phthisis by atmospheric medication and the inhalation of antiseptic vapours has for several years engaged the attention of Dr. W. H. Spencer of St. Leonards-on-Sea, who in 1891 published an account of the vaporiser which he had been employing for the previous four years. The apparatus has since then undergone some modifications, and in its present simplified form is sold by the "Arema" Manufacturing Company, 27, High Holborn, W.C. It consists essentially of a water-bath, which is kept at a constant temperature by means of a special oil lamp. The body of the lamp is about three inches in height and stands on a wooden disc six inches in diameter, which supports a stout upright wire frame twelve inches high. The water-bath slides vertically in this frame, so that it may be placed at any required distance above the lamp. The upper part of the water-bath contains the substance to be vaporised, which will usually be one of the volatile oils, such as eucalyptus oil or terebene, and of which about an ounce or an ounce and a half will be used every twelve hours. The lamp holds rather more than two ounces of oil, which should be the best French colza, and lasts for about twelve hours; the wick is about five-eighths of an inch long and is carried in a holder which floats on the oil. The water in the outer pan of the water-bath is kept at a temperature of about 180° F. and requires renewal every twenty-four hours. The entire apparatus is simple, portable, and easy to manage.

AN INVALID CUSHION.

WE have received from Messrs. Thos. J. Syer and Co., 45, Wilson-street, Finsbury, E.C., a new pattern of horsehair cushion which is very convenient and comfortable and may be used in an ordinary chair. Like most articles of the kind, it is provided with ties passing quite through its thickness, in order to maintain the shape and prevent the stuffing from being displaced. In this cushion these ties are ingeniously arranged in two lines, so as to give it a wedge shape and prevent pressure on the sciatic nerve. Pressure on the sacrum is effectually avoided by a recess in that part of the cushion which is furthest from the edge of the chair.

MEDICAL BOOK-KEEPING.

IN connexion with my system of medical book-keeping I have felt that some means of making notes on cases ought to be provided, but it was impossible to make this addition to the book itself without great additional expense in interleaving and increasing the size unduly. To meet this requirement and to obviate the difficulty, I have designed "Memoranda Leaves," alphabetically arranged to correspond with the list and day book pages, for temporary insertion each month. At the end of the month these are placed in a box-file and fresh ones inserted, so that a record of each case can be found in a moment. The dates, which follow each other successively, and the names are arranged in columns at the end of each page, with printed headings, so that in referring it is only necessary to turn over the pages in the same manner as the page of a book is sought for. The "Leaves" are sent out (by Messrs. Silverlock) in sufficient number to last the six years that the book lasts, and each box-file thus contains the notes of all cases during that period. They can be obtained bound as a separate volume, but the loose leaves are more convenient in a busy practice.

W. WRIGHT HABDWICKE, M.D.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 21, 1895.

WE have from time to time animadverted upon the rosy view taken by some of our contemporaries and others in regard to the tampering of food, and the contrary opinions we have given expression to are now officially stamped as correct by the disclosures contained in the second Blue-book of the Food Products Adulteration Committee, which, however, deals with only a part, but a very important part, of the subject—viz., the evidence of those connected with the wholesale trade. None the less one fact stands out prominently, and it is with no little satisfaction that we observe it, and that is that the malpractice most to be complained of now is not the use of adulterants of an unwholesome or even poisonous character, but simply the addition of cheaper substances, perhaps to improve the appearance, but more probably to add to bulk. Thus the public have little to fear in regard to injurious admixture, though suffering largely from deception. Moreover, the deception and fraud, it would appear, are as a rule the acts of the wholesale vendor rather than of the retailer or small shopkeeper. He would have been sanguine indeed who expected that the action of the memorable Analytical Commission of THE LANCET in 1850 would have entirely stamped out every shape and form of food and drugs adulteration; still when the gross practices then shown to exist, and brought to light by the founder of THE LANCET, are called to mind, there can be but little doubt of the excellent results of this inquiry—an inquiry which was fraught with tremendous issues and responsibilities. It must surely be conceded that credit is justly due to the late Mr. WAKLEY when a present day Blue-book records that adulteration with substances injurious to health is practically a thing of the past, and that although fraud is yet existent it is practised, not so much by the shopkeeper, who was the principal offender brought to justice by THE LANCET inquiry, as by the wholesale dealer, *whom the operations of the Food and Drugs Act do not reach*. Hitherto it has been the retailer who has been mainly controlled in regard to the sale of food, and on this account injustice doubtless has frequently been meted out to him. The remedy for this state of things is obvious and will no doubt be provided when the members of the Committee draw up their important report. Already, however, the evidence contained in their second Blue-book shows how great a public benefaction was THE LANCET'S initiative in the matter of a perilous crusade against adulteration nearly fifty years ago. In those days it was chiefly the shopkeepers who were convicted of gross fraud, and in many instances of selling articles of food sophisticated to a serious extent with injurious substances. The evidence of the Blue-book now shows the absolute necessity of applying the law to the manufacturer and to the wholesale importer, who has no doubt often escaped punishment wrongly inflicted on the retailer, the latter doubtless in some cases having been unconscious of selling a fraudulent article. The evidence on this matter is all the more convincing because it comes from large traders and trading associations who are desirous of stopping these malpractices.

We gather the following conclusions from the statements sworn to before the Committee by some of the leading representatives of the grocery trade. Butter is adulterated to a large extent, a great quantity of it being imported; the adulterants are chiefly foreign fats, while an excess of water sometimes over 40 per cent. is frequently met with. Spurious cheese is largely imported from America, and in smaller quantities from Hamburg and Holland; the so-called filled cheese is composed of skimmed milk, lard, "oleo oil," and other foreign fats. Cocoa is supplied either concentrated by the elimination of its 50 per cent. of fat or attenuated with starch and sugar; in the absence of a definition, however, for pure cocoa it is difficult to institute proceedings unless the admixture is proved to be unwholesome. Coffee is largely adulterated, and the gradual decrease of its consumption is probably due to the unscrupulous way in which it is mixed with chicory. Milk is the subject of considerable adulteration, and attention is drawn to the fact that large quantities of milk and cream are now imported without any precautions being taken to ensure their freedom from infection and impurities. Lard does not appear to be seriously adulterated, although admixtures are sold containing cotton-seed oil or beef stearine, but at a much lower price than that of pure lard. Oatmeal in one instance proved to be adulterated with barley meal. Olive oil is largely worked up with cotton and other oils. Pepper has been the subject of extensive adulteration with ground rice, "long pepper," olive stones, &c., although the practice has received considerable check by the vigorous application of the Sale of Food and Drugs Act, 1875. In the case of certain imported goods the Act has, however, been powerless; in one notorious case 70,000 lb. of so-called pepper dust, consisting of 1 per cent. of pepper and 99 per cent. of sand and clay, were offered for sale and disposed of by public auction in Mincing-lane. The desirability of extending the Act so as to make it include wholesale dealings is also manifest in the following case; a consignment of so-called salvage pepper, which had been soaking in Thames water and was saturated with rotten matter so as to be offensive, was disposed of at Mincing-lane to the extent of 240,000 lb. Instances of spurious drugs have likewise occurred in this connexion. Thus a quantity of gum kino was offered for sale by the brokers which "was no more (we are quoting Mr. UMNEY) like kino to the initiated than chalk is like cheese." Similarly spurious buchu leaves are palmed off as genuine ones, and false ipecacuanha for true. Cane sugar is largely replaced by beet sugar, which is ingeniously coloured with aniline dyes to imitate the superior and higher priced article. Spirits are chiefly diluted with water, but the publican contracts himself out of the Act by setting up a notice that "all spirits sold are diluted." In regard to ginger it is said that the trade of the country is being destroyed by the adulteration going on, the practice usually consisting in grinding up refuse or exhausted ginger with the genuine article. Liquorice, especially that imported from France, is heavily adulterated, principally with rice, starch, sago flour,

Digitized by Google

miller's sweepings, and other substances which often induce the presence of weevils and maggots. Caraway seed appears to be deprived of much of its oil and to be then sold mixed with genuine seed in the same way as ginger. Cinnamon has also been found to be adulterated with ground walnut shells, which, of course, are quite worthless. It is unnecessary to extend this list, but it is quite evident that the sooner the scope of the Act is made to include the wholesale trade, the factories, and the port of entry in the case of imported goods, so much the better will it be. Against all this it is satisfactory to record that the retail pharmacist's dealings have on the whole been most creditable.

A word on the administration of the Acts must not be omitted. There is no doubt that the Act of 1875, *so far as its scope went*, has done excellent service in the prevention of adulteration and has raised the standard of purity to a very creditable position, and this despite its shortcomings in regard to the details of its practical working. The Food and Drugs Act is a huge piece of legislative machinery, and it would have been surprising if breakdowns had not occurred. The time has come, however, when not only its scope should be extended, as we have already indicated, but when its administration should be strengthened and enforced. The Act is, as it were, just passing out of its experimental stage, and we are learning its defects. These defects must, indeed, be now patent to the members of the Committee, who will, doubtless, recommend to Parliament the desirability and necessity of making speedy reforms and of effecting some important administrative changes. As the evidence already shows, the system of taking samples needs modification, some greater control over the action of inspectors is wanted, a greater uniformity in magisterial decisions in adulteration cases is desirable, the scale of fines should be uniform and commensurate with the offence, and so forth. Lastly, there is the question of standards, and of a court of appeal, and of the emoluments and the qualifications of the public analyst. We hope to return to these subjects at a future time, but the direction in which legislation is needed on these points has already been indicated, and we confidently expect that a new Act more in accordance with the requirements of the present day, when it is largely a case of setting science to catch science, will arise Phœnix-like out of the ashes of the old one, which, nevertheless, has done the community excellent service, and which we are justly proud of reminding our readers had its origin in the famous Analytical Commission which was set on foot by THOMAS WAKLEY, the founder of THE LANCET, solely in the interests of the people's good and well-being.

IT is not much more than half a century ago that the executors of a clergyman sued the Providence Assurance Company for £2000, the amount of an insurance effected upon his life, when, after hearing conflicting evidence on the point, the judge left it to the jury to decide whether insanity had a tendency to shorten life, instructing them that if they decided that insanity had such a tendency they must find for the defendant, and, if it had not, for the plaintiff. After a short deliberation the jury found for the plaintiff on the ground that insanity had no tendency to shorten life. This case was referred to by the late Dr. WILLIAM FARR in his well-known paper, read before the Royal Statistical Society in 1841, entitled "Report on the Mortality of Lunatics," as an nstructive commentary on the misconception that then existed as to the effect of insanity upon mortality. Dr. FARR in this paper, from such statistics as were then available, came to the conclusion that "the mortality of severe cases of insanity cannot, I think, in favourable circumstances, be less than 6 per cent. (annually); so that the mortality is three times greater among lunatics than among the general population at the same age." Mr. NOEL A. HUMPHREYS, in his paper read before the same society in 1890 on Statistics of Insanity in England, deplored the fact that since Dr. FARR wrote on the subject so little progress had been made in the recording of statistical data on which more definite information concerning the influence of insanity upon mortality could be based.

Since the last-mentioned paper was read the Lunacy Commissioners have added to their reports a new and valuable table, which will before long supply the much-needed material for calculating the precise effect of insanity upon the rates of mortality of males and of females at different ages. Although the full value of these tables cannot be attained until they are available for a series of years, it may not be without interest to note some of the results shown in the table referred to, which appears in the recently issued forty-ninth report dealing with the insane patients known to the Commissioners on Jan. 1st last. It should be stated that the table now under notice relates to the rates of mortality among the insane in various kinds of asylums during the year 1893, which are calculated upon the numbers of inmates of those asylums on Jan. 1st in that year. It may be noted, in passing, that the calculated death-rates in this table would have been more correct had they been based upon the mean numbers of inmates at the beginning and at the end of the year during which the deaths occurred—namely, on Jan. 1st, 1893, and Jan. 1st, 1894. The effect of the method adopted by the Lunacy Commissioners is slightly to overstate the rates of mortality, but this scarcely invalidates them for comparison with the death-rates at the same groups of ages in the general English population. Among 30,533 male inmates of asylums on Jan. 1st, 1893, the death-rate per 1000 during the year 1893 was lowest, 77·4, at the age period twenty-five to thirty-five, and steadily rose to 352·5 among the small number living at the ages seventy-five to eighty-five. Thus the mortality of the insane, as of the general population, naturally increases with age. It is, however, very interesting to note that the excess of mortality due to insanity is far greatest at the earlier ages, and declines steadily to the end of life. Taking 100 to represent the rate of mortality among males in the general English population at each successive age period, the mortality among the male insane was 2237 at from fifteen to twenty, 1409 at from twenty to twenty-five, 1046 at from twenty-five to thirty-five, and 867 at from thirty-five to forty-five. At subsequent age periods the proportion to 100 declines still more rapidly from 519 at from forty-five to fifty-five to 246 at from seventy-five to eighty-five. It is scarcely

Digitized by Google

necessary to point out that the far greater relative excess of the mortality of the insane at the earlier ages is due to the much larger proportion of acute cases among the inmates of asylums under forty-five years of age. This is a point on which further statistical information would be both interesting and valuable. The mortality statistics of the female inmates of asylums give very similar results. It may be noted, however, that the rate of mortality in 1893 was lowest — 63·3 per 1000—at the age period forty-five to fifty-five, and at later periods rose successively to 270·9 at the seventy-five to eighty-five period. The rate at each age period was very considerably lower than the male rate at the same age. Consequently, the excess of mortality due to insanity was also far smaller among females than among males. The relative excess of female mortality was, however, as in the case of male mortality, greatest at the earlier age periods and steadily declined to the end of life. The death-rate among the female insane at the age of fifteen to twenty years was 1547 to 100 among the general population, at twenty to twenty-five years it was 1254, and at twenty-five to thirty-five years it was 893; the proportion to 100 further receded at subsequent age periods, and at seventy-five to eighty-five years it was only 208. The Lunacy Commissioners in their table compare also the mean mortality of the insane at all ages with the general English rate at all ages. This comparison is, however, absolutely valueless and misleading, unless correction is made for the abnormal age constitution of the insane population, which includes no infants and but few children, and a very excessive proportion of persons over sixty years of age.

It would be unwise to attach too much importance to this consideration of the Lunacy Commissioners' valuable figures for a single year, but it is safe to conclude that Dr. FARR very considerably understated the effect of insanity upon English mortality when he said that the mortality of the insane "is three times greater than among the general population at the same age." In 1893 the rate of mortality among the inmates of the English asylums, male and female, between the ages of twenty-five and fifty-five, when the inmates are most numerous, was more than six times the rate that prevailed at the same ages among the general English population.

IT is possible, and even probable, that the electrical conditions of the atmosphere have an important bearing on bodily health. As evidence of this may be instanced that tendency to headache, irritability, and general malaise experienced by many persons just before a thunderstorm. Amongst the conditions that predispose to sunstroke in India there has been noticed that peculiar condition of the air "in which the hairs of a horse's tail repel each other, in which the hairs of the head stand on end, in which a man exposed to its influence becomes irritable, headachy, and restless without knowing exactly what is the matter with him." Various observers have remarked that a thunderstorm is often preceded by an increased frequency of cases of heat apoplexy. Whether this phenomenon be strictly attributable to electrical conditions, to the heat, to some alteration in the respirability of the air, or to other causes, it is difficult to determine.

As to the source of atmospheric electricity there are many hypotheses, but little positive knowledge. The problem of the thundercloud still awaits solution; yet this would seem only to require a series of well-arranged laboratory experiments on a sufficiently extensive scale. In the meantime it is safe to say that the electrification of the air is in some way connected with the presence of water. Whatever be the determining cause, the air before a thunderstorm becomes charged with electricity, and a charge of opposite sign is induced upon the earth; in other words, the difference of potential between the earth and the air goes on increasing. The body of a man standing on the earth's surface, and having, therefore, the earth's potential, may be regarded as a discharging point doing its best to effect the restoration of electric equilibrium between the earth and the air in its vicinity. This process will continue until, either by a steady discharge or by the disruptive discharge of the thunderstorm, tension is relieved and equilibrium is effectually restored. The man has really been suffering from an accelerated rate of electrical discharge. Now if his body be regarded as a connexion between earth and air it is to be remembered that the difference of potential between the two latter, and therefore between the head and feet of the man, is subject to various sudden and extensive fluctuations. A potential difference at one moment of 100 volts or less may in a few minutes rise to the same number of thousands. Experimenting in the Isle of Arran, Lord KELVIN found the difference of potential between the earth and an insulated burning match at a height of nine feet to vary from 200 to 400 volts, and "during breezes from the east and north-east it went up to 4000 volts." He points out that "the gradual variations minute after minute through so wide a range as three or four to one, and not infrequently rising to twenty times the ordinary minimum, must have been due to positively electrified masses of air within a few hundred feet of the place of observation, wafted along with the gentle winds of five feet or ten feet or fifteen feet a second." If, therefore, the body be subjected to such variations of potential as occur in fine weather between the earth and the electrified masses of air of which Lord KELVIN speaks, much more formidable must be the conditions that exist between the earth and the heavily charged thundercloud. The animal body, accustomed as it has become to its electrical environment, and little sensitive to the slighter fluctuations of potential, may nevertheless be seriously influenced by the severer manifestations of the thunderstorm. Questions of this kind raise some interesting points in connexion with the therapeutic use of the so-called electro-static bath. This consists, as is well known, of the simple placing of the insulated body in connexion with one or other pole of the static machine. Not that under these conditions the electricity is strictly "static" or at rest; the body of the patient is traversed by a current at very high potential which completes its circuit through the air. It is stated that with a four-plate Holtz machine the insulated body was brought to a potential of 30,000 volts, the current passing being about $\frac{1}{1000}$ of an ampère. For this procedure there are claimed well-determined physiological effects, such as increased action of the skin; an influence on blood pressure, as shown by

Digitized by Google

sphygmographic tracings; an increase in the frequency and the depth of the respirations; as well as increased excretion of urea and phosphates.[1]

Now, reverting to what has been already stated, it is evident that a living body exists on the earth under definite, although changeable, electrical conditions. In point of fact, it lives and moves and has its being in an electro-static bath. The kind of bath—that is, the electrical condition of the air, and therefore of the earth—varies with the weather. There seems to be "a normal fair weather positive of natural atmospheric electricity." On a cloudy day the sign varies. How far do facts of this kind help to explain the influence of weather upon health? It has been suggested[2] that, inasmuch as the neurasthenic, the gouty, the rheumatic, and persons suffering from diseases of the spinal cord are better on a clear day than on a cloudy one, the indication is to treat them by negative electrification. It must be in the highest degree difficult to trace such effects to the electrical rather than to the hygrometric or other conditions of the atmosphere; still, vague as such conjectures are, it is not impossible that the electrical condition of the air may eventually furnish the key to treatment by the electro-static bath.

Annotations.

"Ne quid nimis."

STATE BACTERIOLOGY.

PROBABLY the Medical Department of the Local Government Board never stood so high in public estimation as it does to-day. The experience of its work done in the best interests of public health and for the furtherance of sanitary science during many years past has been such as to claim the gratitude of the nation again and again. Yet it is in such circumstances that our contemporary the *Daily Chronicle*, in its issue of the 14th inst., takes pains to dilate in a lengthy leading article on the so-called "bacteria madness" of the Medical Department. Dealing with the recently issued volume of 1893–94, the paper speaks of "its 500 pages of microscopic portents." Save in so far as all the work of the Department, of whatever character, savours of a "microscopic" regard for precision of fact, the statement is a serious exaggeration. The report in question consists of 556 pages of printed matter, and less than 100 of them are devoted to bacteriology as applied to sanitary science, and this in the sole State-issued document on such a vital subject. In the other 400 and odd pages we find discussed at length such matters as vaccination, water-borne enteric fever, cholera prevalences, lead poisoning by water-supplies, epidemic skin disease, and the like, so that the "bacteria madness" sinks into comparative insignificance and is, moreover, relegated to the end of the volume. But if it were not so why decry, as our contemporary does, bacteriology as an adjunct to public health work? Surely the *Daily Chronicle* and its readers will not readily belittle the part played by the bacteriological laboratory in our recent cholera panic of 1893, or the advantage it is now affording towards the prompt diagnosis of diphtheria; or the significance of the present day knowledge, by the aid of bacteriology, of disorders in the lower animals which have an important bearing on certain infectious diseases in man. The value of disinfection of one and another kind, too, has only been ascertained with any degree of certainty by laboratory experiment, and these are but instances of our indebtedness to bacteriology. It is, as a branch of preventive medicine, of necessarily slow progress; and it is often only by years of patient research that definite practical results are arrived at. But perhaps the most absurd view taken by the *Daily Chronicle* is that of the professional experts at Whitehall being "glued to their microscopes." We have searched in vain to find the name of any one of the bacteriologists, details of whose work find place in the volume in question, among the staff of the medical inspectorate. Just as their work is a subsection of public medicine, so these workers are themselves only from year to year attached to the Public Health Department, and only supplement the clinical and etiological observation of disease by the aid of the microscope and the culture tube. The truth of the matter is that the nation has at Whitehall a small body of sanitary experts whose whole time is occupied in the duty of safeguarding the public health in the broadest sense of the term, and to whom the community is glad and able to look with full confidence in any time of national danger by reason of formidable threatenings of disease.

ANTHROPOPHAGI AND MOTHERS-IN-LAW.

THE Anthropological Section of the British Association had a most interesting meeting on Sept. 14th. The first paper was read by Mr. Myres, and consisted of an abstract of the report of the committee appointed to investigate the North-Western tribes of Canada. In British Columbia there is a tribe known as the Ts'ets'a'ut, among whom is "found the custom of avoidance between mother-in-law and son-in-law (*Matuo Ha*) which was common to all the Tinneh tribes. They were ashamed to talk to each other or even to see each other." The custom of avoidance of mothers-in-law is, we fancy, not unknown among tribes which have attained a higher degree of civilisation than the Ts'ets'a'uts, but these untutored people have an advantage over their more superior brethren in that among them the avoidance is mutual, while in the records of the Newcome and Lovel families it is noted on the authority of their biographer that neither did the Campaigner avoid Clive Newcome, nor did Lady Baker avoid Frederick Lovel. From this subject the session passed to consider the subject of cannibalism. It is the tendency of the age to modify if not to entirely alter preconceived notions as to the wickedness of those whom we have been brought up to believe were monsters of iniquity. Thus the gracious sovereign lady whom we were all taught to stigmatise by the opprobrious epithet of "Bloody" has lately been shown to be a lady of most mild and merciful disposition. Blue Beard, if not absolutely harmless, was merely an involuntary sufferer from "psychopathia sexualis," and now we have the whitewashing of the cannibal. Captain Hinde, who has been travelling and fighting for some years, was the courageous person who took upon himself to show that the cannibal has, after all, many lovable traits. True, he is somewhat cruel in his ways of preparing food; for instance, "certain tribes of the Bangala race themselves acknowledge that they break the arms and legs of the victim, and place the body thus mutilated and still living in water for two or three days, on the supposition that this pre-mortem treatment renders the flesh more palatable." But this is no worse than our forefathers' custom of whipping pigs to death, or roasting geese "quick" as the incomparable Sidonia did. After a fight Captain Hinde's followers invariably ate up the killed, a method of "disposal of the dead" which has its merits. Cannibalism probably originated in the religious idea that the godhead was incarnated in

Digitized by Google

some human being or animal, and that by eating this the eaters became imbued with some spark of divinity. In the lower races the idea of divinity was lost and only the qualities of bravery or strength remained. It may be said with all reverence, as one speaker pointed out, that the deepest mysteries of the Christian religion are founded on this, and closely connected is the Holy Grail legend, the Christianised form of a Pagan semi-cannibal myth. It would take up too much space to enter into all the branches of this subject—corpse cakes, mell dolls, ancient sacramental rites, the swallowing of the children of Cronos—but we have said sufficient to show that in a custom regarded with abhorrence by all modern races there lurk some faint traces of the universal longing for something higher than our mere humanity.

THE PLAISTOW MATRICIDE.

THE above case is one of the most remarkable in the history of legal medicine. A crime more revolting, foul, and unnatural it would be difficult to conceive, and its only extenuating feature is that it was committed by a person who, according to the finding of the jury, was irresponsible for the act. On July 13th last Robert Allen Coombes slew his mother by stabbing her in the heart whilst in bed with her. There is ample proof that the murder was premeditated and carried out in the most cold-blooded way. The prisoner, acting in collusion with his younger brother, having determined to kill his mother, carried out his fell purpose in the manner described. He then covered up her body and with the proceeds of the robbery of the effects belonging to his parents indulged himself in attending cricket matches. It was not until many days after the murder that the crime was discovered. At the inquiry of a relative as to what had become of his mother the lad, after prevarication and lying, boldly confessed that he had compassed the deed, and that the corpse was lying in a room adjacent to the one in which he was playing cards with his brother and a sailor named Fox. The latter was indicted as being an accessory after the fact, but there was no proof that he knew that Coombes had murdered his mother or that he was aware of the presence of the corpse in the house. A curious legal point arose at the trial at the Central Criminal Court—viz., whether Fox could be convicted as an accessory after the fact if the murder was committed by Coombes whilst in a state of insanity. Mr. Justice Kennedy, after consulting the authorities, uled that as the felonious act of an insane person was not legally a crime Fox must be acquitted if the jury found Coombes to have been a lunatic at the time when he killed his parent. This in effect was their verdict, and so, independently of the merits of the case, Fox was acquitted. We are not in a position to traverse the reading of the statute, and although the above interpretation may be good at criminal law it certainly strikes us as running counter to the dictates of common-sense. The younger Coombes was certainly an accessory before and after the fact, but as he was to a great extent under the domination of his brother it was wisely decided not to proceed against him. Had the charge been pursued it is probable the jury would have acquitted him. It is to be hoped that with such a fearful past he will not be allowed to shape his future for himself. Robert Coombes, whom the jury found to have been insane when he murdered his mother, was a good instance of a particular type of insanity. Judged by the strict letter of the law, which holds that the proof of insanity is the knowledge of right and wrong, and consequently of the nature and quality of the act, the contention of the prosecuting counsel and the direction of the learned judge can well be understood. Coombes was not suffering from intellectual insanity, and this is the only form recognised as relieving from criminal responsibility; but his life-history points to moral alienism as his usual state and to impulsive homicidal mania as the culminating feature of his mental disorder. He seems from the evidence to have been brought into the world by instrumental aid, which had left permanent marks. Years ago he had to be treated for severe headache. Of course it may be asserted that the carelessness with which he viewed his position after committal, and the recklessness with which he spoke and wrote on the matter of his trial and its possible issue, were assumed in order to mislead the medical officer of the prison and others, and thereby construct a defence against the capital charge. We hold, however, that it is far more likely that a boy, however deep his moral depravity, would, on realising and reviewing such a monstrous and unnatural crime, be seized with remorse and shame. Again, although there was some motive for the act, the evidence conclusively shows that it was totally inadequate. After a careful consideration of the case in all its aspects we unhesitatingly endorse the verdict of the jury. To have convicted Coombes would have been an injustice; to have sacrificed his life would have been a crime. It is matter for congratulation that the sound common-sense of the jury prevailed over what was probably the strict interpretation of the law in its bearing on criminal responsibility.

IS THE SMOKE NUISANCES ACT PROPERLY ENFORCED?

NOT the least important section of the Public Health Act is that which gives power to local authorities to compel the owners of factories &c. to prevent nuisance arising from the escape of smoke and worse emanations. Any chimney (not being the chimney of a private dwelling-house) sending forth black smoke in such quantities as to be a nuisance may be dealt with summarily under this clause of the Act. Yet those who journey to and from the suburban districts every day must have observed that in a great majority of instances this useful Act is not applied as it should be. Indeed, there is every appearance that it is most wantonly disregarded. Within a circle of about four miles' radius outside the city of London several, if not the majority, of London's factories are situated, and these, comprising glue works, soap works, match works, chemical works, not to mention other offensive trades, may be seen every day vomiting forth heavy black smoke which eventually enshrouds in hideous murk and gloom just those densely populated places where pure, fresh air is most needed. We have reason to believe that this offence is being committed on all sides of the metropolis. We will, however, quote one instance of which we have had ocular demonstration. Travellers by that branch of the Great Eastern Railway running between Bow and Stratford can count a score or so of chimneys connected with the factories of this low-lying district emitting huge volumes of densely black smoke in the most outrageous manner, and it is well known that when a tendency to fog exists it is between these points, as the railway officials must find to their cost, where it is thickest and most persistent. It not infrequently happens also that the passengers are sickened by the offensive smells pervading the compartments as the train passes through this district. The evil is, of course, accentuated by the train stopping, when the ordeal becomes really severe. We have reason for believing that similar nuisances exist elsewhere at places a few miles out of the city, so that, however fresh and pure the prevailing wind may be, and in whatever direction it blows, some gloom and contamination must reach the inner metropolis. We trust that the authorities may be roused to action in this matter and take immediate steps to bring to book any offender, especially as he can avail himself of simple means by which the production of objectionable smoke may be immensely minimised. We

Digitized by Google

might point out that now is the time to act, before the mischief is accentuated by sudden changes of pressure and temperature, and before the subject is brought forcibly home to us by the onset and prevalence of a real "pea-souper."

THE CHITRAL FORCE.

THE latest Indian papers contain several items of interest about the late expedition to Chitral. Surgeon-Major Sir George Robertson will have arrived ere this at Chitral and have declared the intentions of the Indian Government. As soon as the reports from Sir Robert Low and General Stedman have been considered the Government will settle the final details regarding the camps and fortified posts that are to be occupied. In the meantime the Chitral Relief Force is being rapidly broken up, and the European regiments have returned to India without the exhibition of any hostile signs on the part of the tribes during their withdrawal. The losses from disease and exposure in the field have, as usual, far exceeded those attributable to casualties in action during the late expedition. Enteric fever is stated to have prevailed among the troops on the highlands beyond the border, just as it does among troops in their cantonments, and to have caused many deaths; but no cholera has occurred so far among the regiments during their return march, such as, it will be remembered, took place on the return march of the force from Gandamak in the Afghan campaign of 1878–9. Cholera was then prevailing in a severe epidemic form, which is not the case at present, and this fact makes all the difference. Fever is, however, very common in the Peshawar Valley at this season and has to be taken into account. But the Indian authorities are stated to have taken great care as to their sanitary arrangements, camping grounds, and the transport of the troops and their prompt entraining at Nowshera.

ARTISTIC OR HYGIENIC LONDON?

IT is idle to deny that the discussions which the daily papers open their columns to in the "hungry" season are useful and instructive, if not productive of practical good. The subject of beautifying London is one, for instance, upon which everyone is entitled to contribute an opinion, and out of a crop of suggestions a few surely are certain to be feasible and worthy of consideration. Invariably, however, there are those—or at least there is certain to be one—who think that other questions of reform are more pressing. And the suggestion that we should turn our attention to the sweetening and cleansing of the air of our streets and to the removal of effete animal products is a case in point. On hygienic grounds it should be considered first, while from an artistic point of view even the effect upon the nose surely requires as much studying as the effect upon the eye. An eyesore is comparable with a stench, but the removal of the latter first would, we imagine, be the step preferred by most people. The atmosphere of our streets is very often loathsome and sickening, especially when the weather is warm and when there is an absence of breeze. The offensive smell is due in the main to the effete gaseous, liquid, and solid products given off by hard-worked horses, and as long as horses are used in our streets it is not easy to suggest a remedy beyond that now applied—the speedy removal as far as is possible of these products by scavengers. When street locomotion comes to be accomplished by means of steam or electric power or by means of petroleum motors—a day that may not be far distant—we may hope to have 'no complaining in our streets" of the filthiness of the atmosphere, but what will those who clamour for the beautifying of London have to say to such a horribly inartistic idea? We might remind them, also, of a third sense that is rudely assailed in our streets—that of hearing—but we may hope that this will soon be in part mitigated by the general adoption of the rubber or inflated tyre. We have nothing to suggest but legislative measures to clear the streets of "the special editions" and other itinerant cries, besides "the music" performed gratis to the passers-by. But who shall say which attack on these three senses is the least nuisance, and which affects most prejudicially the health? Each is an important factor in this connexion, since we know the restorative value to health of a change of scene, of a change of air, and of quiet.

A QUESTION OF RESPONSIBILITY.

TWO men were suffocated in a cistern at Bristol last week under very unusual circumstances. Some defective drains were found in the house of a dental surgeon, and when the drain was opened it was discovered that a rain-water pipe led directly into a cistern. The cistern was on the cellarage floor, and access was obtained to it by means of a manhole. A pipe also led from a photographer's into the tank, and the chemicals used in his work would drain into it. It was advised to clean out the cistern and fill it up with rubble, so as to get rid of any nuisance, as well as the cistern itself. The contents of the tank were pumped out to about twelve inches from the bottom; this sediment the unfortunate men tried to remove, but they were quickly overcome by the sulphuretted hydrogen gas which was liberated by the disturbance of this sediment. They both expired before any assistance could be given them. This gas was the product of special chemical action by the percolation into the tank of the waste preparations used in the process of photography. At the inquest the coroner stated that there was no criminal negligence of any sort. Certainly the case is most exceptional, and the question of responsibility is practically incapable of solution.

DIPHTHERIA IN LONDON.

DIPHTHERIA prevalence in London is now again as it was in the beginning of August, when the school holidays were commencing. Before that period, and during the month of July, the amount of diphtheria in the metropolis was larger than it has been since, but during the three weeks that have elapsed since the board schools reopened after the summer vacation the recorded attacks have been again growing in number The facts seem to show that, although the closing of the schools may have had little influence on diphtheria mortality in London, yet the closing had a marked effect on the number of sufferers from the malady. Thus in the month of July the weekly record of attacks averaged some 275; in the succeeding four weeks of school holidays this average fell to just over 200; but in the subsequent three weeks it has again risen to 220. In the matter of liability to attack the school holidays have therefore saved children to the extent of some 35 per cent., but the resumption of school work has in the three weeks in question quite obliterated the good results of the holidays. With reference to fatality, the deaths from diphtheria in July averaged 47 weekly; during the month of school closure the average only fell one point, whilst in the subsequent period of three weeks the average was reduced to 44. Last week the number of deaths was 21 in excess of the corrected decennial average for the corresponding week of the years 1885–94. Much the same thing took place last year, but on a somewhat smaller scale, for this year there is a larger prevalence than during 1894. The weekly average of cases in July, 1894, was 200, and in the following month of school holidays it fell to 190, with a further fall to 184 in the next three weeks. But the deaths, while 44 per week in the month preceding and the three weeks following school closure, were

Digitized by Google

as high as 55 per week during the holiday period. Thus, in 1894 the three weeks after the holidays showed a continued fall in the amount of the disease and a substantial fall in its fatality as compared with the time of actual closure. Still the facts point to much good resulting from the release of children from the aggregation inevitable in school. In London there were 55 deaths last week, as against 24, 40, and 38 in the three weeks before; all but one being in children and persons under the age of twenty years. There were 5 deaths each in Mile End Old Town, Poplar, and Greenwich, and 4 each in Hackney and Lambeth sanitary areas. The admissions to hospital were 105 as compared with previous weekly figures of 81, 86, and 78, and the mortality was about 22 per cent. of the attacks. There remained in hospital at the close of the week 663 patients, a number only slightly varying on successive Saturdays for several weeks past. In the metropolitan outer ring 14 deaths were attributed to diphtheria, and among these 8 were those of persons belonging to the West Ham registration district.

DEATH IN BANK-NOTES.

ACCORDING to *L'Indépendance Belge* the cashier of a Viennese bank met with his death a short time ago under circumstances as remarkable as they are happily rare. Having to count a large number of used bank-notes, all more or less soiled and difficult to separate from each other, he incautiously, and in spite of a friendly warning regarding the risk he was thereby encountering, endeavoured to facilitate his work by moistening his fingers and thumb with his saliva. The same evening he felt a tingling pain in his lips, but did not pay much attention to the symptom, thinking it would pass away. The next morning, however, as his mouth and tongue were hot and swollen, he began to feel alarmed, and without loss of time consulted a medical man, who is said to have forthwith incised the tumour. What the effects, immediate and remote, of this procedure were we are not told, the remainder of the history being briefly summed up in the following terms: "Notwithstanding the operation the patient died three days subsequently from the effects of the poison which he had absorbed." There are some points in this case, as set forth by our lay contemporary, which require elucidation. It is to be hoped, therefore, that an account from a qualified source will be forthcoming.

AN INEBRIATES BILL.

THE medical profession in Austria is to be congratulated on a success recently attained by views which have long been maintained by its members in common with their brethren in other parts of the world. The position of the drunkard in social life has hitherto been regarded in some quarters as an anomaly not so nearly related to the state of lunacy as to justify its treatment on similar lines. There has always existed a feeling that the craving for drink with its consequences ought to be treated as a mere bad habit, a temporary and recoverable error, not really a form of mental disorder. At last there are signs of a return to sounder reasoning. As announced by our Vienna correspondent in our columns last week a Bill now about to be submitted to the Austrian Reichsrath proposes to treat the persistent drunkard as mentally incapable. As such he shall be restrained from injuring either himself or others dependent upon him. This restraint may take the form either of voluntary or compulsory detention in specially appointed retreats. In cases where the confinement is compulsory, provision is made for a regular trial in which witnesses, both lay and medical, will be heard. The justification for detention will consist in such facts as repeated previous convictions of drunkenness, proof of danger to life, and other evidence strong enough to leave no doubt that the alcoholic passion has become ungovernable and has rendered its victim morally or economically a source of danger to himself or others. The term of detention will be two years, and this term is liable to reduction or renewal as occasion requires. The Bill may be taken as fairly representing medical opinion on this subject. Modifications in detail may, perhaps, be found advisable as time goes on, but the measure cannot but be approved on its general outlines. As the first practical attempt to deal candidly with the drink craving, and to treat it as what in very many cases it is—a masterful and engrained vice which has really absorbed all traces of a resisting will—it deserves, and we hope it will receive, a fair trial. We entirely fail to see how injustice can be complained of under such an Act as this, where every precaution is taken to render the preliminary investigation as searching as possible, where no personal privilege is lost by detention, and where the patient's own interest will be served in a degree at least equal to that of his relatives and friends.

INTRA-CRANIAL OPERATIONS ON THE FIFTH NERVE.

IN a recent number of the *Neurologisches Centralblatt* an abstract is given of an important paper on this subject by F. Krause which appeared in the fiftieth volume of Langenbeck's *Archiv;* of eight cases operated upon by him only one died, a man aged seventy-two, whose death occurred, six days after the operation, from heart failure due to atheroma of the coronary arteries. The others all did well, and in no case in which there was total removal of the ganglion has any recurrence of pain as yet taken place. In the only case in which Krause restricted himself to an operation on the second division of the nerve there was recurrence of pain, and then the ganglion was removed and the pain disappeared and remained absent. A comparison of the cases operated on by Rose's method and those operated on by the method of Krause and Frank Nartley shows a mortality of 18 per cent. in the former and 9·8 in the latter. Curious functional disturbances are described as following the operation. Sometimes there is difficulty in opening the mouth, apparently determined by contraction taking place in the muscles of mastication. In spite of the complete anæsthesia of the cornea and conjunctiva, only in one case was there observed by Krause a slight corneal ulcer, which quickly healed. The masseter, temporal, and pterygoid muscles were weakened on the affected side, but little inconvenience resulted. The peculiar and varying sensory impairment in the different regions is also described, and finally the indications for this very radical operation are clearly set out.

HOSPITAL ABUSE AT BRIGHTON.

A RECENT number of a local paper contains a letter on the abuse of hospitals at Brighton which is well worth the attention of the inhabitants of that favoured place. The letter is by Dr. Francis J. A. Waring and is admirable alike in the spirit in which it is written and the facts which it adduces. Dr. Waring, while making it abundantly clear that the medical profession is unanimous in wishing all deserving cases to have every attention and consideration at hospitals, expresses his conviction that a vast number of persons who can well afford to pay are treated at the various medical charities—to wit, the Sussex County Hospital, the Hospital for Children, Hospital for Women, Throat and Ear Hospital, Eye Hospital, Brighton and Hove Dispensary, and the two Homœopathic Dispensaries. Out of a population of 150,000 no less than 38,113 patients are treated at these charitable institutions. Of 3704 births in Brighton and Hove in 1894 no less than 1240 women, or

Digitized by Google

one-third of the whole, have been attended by one charity alone. Dr. Waring says that it is a common thing for men earning from 35*s.* to 40*s.* a week to say that they have been taking their children to a hospital. Such facts are a discredit to Brighton and to the administration of its charities. They tend distinctly to injure the medical charities by hardening the hearts of those who have the means and the disposition to help them, and they tend to degrade those who are relieved by treating them as if they were paupers. Dr. Waring's letter should be seriously pondered by the subscribers and the committee of every medical charity in Brighton.

THE DIGESTIBILITY OF GASEOUS BEVERAGES.

MM. CARRION AND CAUTRU are the authors of an interesting paper on the Digestion of Gaseous Beverages which was read at one of the Bordeaux Congresses. According to these observers sparkling cider champagne and seltzer water are all endowed with the property of prolonging the digestive process, while at the same time they add greatly to its intenseness. Cider, moreover, is essentially diuretic, and it also exercises a favourable influence on nutrition. It would seem, therefore, that this old-fashioned beverage may with advantage be recommended for use at meals to sufferers from that form of dyspepsia in which the stomach evacuates its contents too quickly, to the detriment of the thereby overworked intestines. In addition to the good qualities already mentioned, well-made cider is reputed to be an efficient corrective of the uric acid diathesis. In Normandy, where the juice of the apple constitutes the staple drink of the lower classes, gout is said to be unknown save amongst the wealthy who indulge in wine. Gravel and stone in the bladder are likewise very rare, and MM. Carrion and Cautru are satisfied that the immunity from both these forms of disease should be placed to the credit of cider.

THE ADULTERATION OF BUTTER IN FRANCE.

THE Central Committee of Hygiene in Paris is to be congratulated on its action with regard to the preparation of butter for exportation, a matter of considerable importance from the point of view of the British consumer. About the year 1876, on the strength of a report drawn up by M. Boullay, in which it was maintained that the admixture of borax and its associates with butter was permissible inasmuch as the addition had never been shown to produce bad consequences, the practice received official sanction and has ever since been habitually resorted to in the trade. In 1883, however, a re-examination of the subject was instituted by competent observers, who came to the conclusion that the continual ingestion of borax was liable to bring about deterioration of the blood corpuscles, and some years later M. Pouchet was able to confirm this dictum from his own investigations. Satisfied with the proof thus afforded, the committee revised its former decision and issued a recommendation to the effect that the employment of borate of soda and boracic acid for the preservation of butter should be made illegal, as in the case of wine. This advice was accepted by Government after deliberation, and in due course a law appeared forbidding the use of borax for the conservation of all provisions, whether destined for home consumption or for export. The first application of the amended ordinance took place recently, when a Normandy butter merchant was tried and condemned for neglecting to conform his practice to its prescriptions. As may be supposed, this new departure has had a most disturbing effect amongst the exporters of French butter, who are loud in their remonstrances against what they endeavour to stigmatise as inconsistency on the part of the Committee of Hygiene. A public body, having once come to a decision on any given subject, should never be allowed to change it under any circumstances, say the would-be adulterants in default of a more logical argument; but they likewise dwell upon the interests of a great national industry already overhandicapped by competition, and wind up a somewhat unblushing petition with the naïve contention that, after all, the butter in question is destined for consumption abroad. Commenting on the matter in *L'Union Médicale*, M. Jules Rochard makes the following sensible observations: "This agitation will cease of its own accord. It is to the interest of our commerce that its products should be above suspicion; in order that they may preserve their good reputation the first essential is that they should be of an irreproachable purity. Borax and boracic acid, like the salicylate of soda, are far oftener employed for the purpose of masking defects in the substances to which they are added than they are for the conservation of sound and wholesome provisions."

EXPLOSIVE LAMPS.

FATAL accidents arising from the use of lamps are happily not very common if we take into account the nearly universal employment of this form of artificial light. Neither is it to be expected that we can, by means of any safeguard known to us, entirely abolish the possibility of their occurrence. Even in regard to this matter no substitute can be found for personal discretion and no code of rules can possibly be framed to meet and obviate the effects of every chance emergency. It has been abundantly proved, however, that precaution may be carried much further than it now is. Such an event as the spontaneous explosion of a lighted lamp while apparently in working order ought certainly to be, if it is not, preventable. The cause in such a case must be due either to a fault of management or of construction. It is already well known that the usual source of explosion is found in the mixed gas of oil vapour and ordinary air which fills the upper part of a partially exhausted lamp chamber. The development of this mixture is, therefore, to be prevented as far as possible, and this object can only be attained by regularly and completely filling the reservoir with fresh oil. Not less important is the relative adaptation of the wick and its holder. Cheap lamps are apt to be defective in regard to this requirement, and they are, in fact, constructed on an explosive principle. In other cases the reservoir is easily breakable, or, again, the pedestal may be unsteady, but it is needless now to go into further details. We would, however, insist very strongly upon the necessity and the duty of obliging manufacturers to supply only such articles as conform to a set standard of security. This duty is well within the power of the Legislature, and it lays no additional burden of cost on the producer, only that of taking due pains in a work which is not in itself difficult. Be the form and finish what they may, certain qualities ought to be legally required in the construction of every lamp. These, already referred to, may again be briefly summarised. They include a broad and firm base, a pedestal of only moderate height, a reservoir of solid material, and a wick and holder accurately adapted to each other. We would have no lamp sanctioned by authority which did not conform to these necessary structural conditions.

THE DIFFUSION OF SMALL-POX.

SMALL-POX in the metropolis last week showed precisely the same features as in several preceding weeks—namely, some three dozen cases, mostly in the eastern and southern groups of sanitary districts. Two deaths from this disease were registered—one each in Lambeth and St. George Hanover-square sanitary areas, one of these cases being an

Digitized by Google

unvaccinated child aged between one and five years of age, and the other an adult concerning whose state as to vaccination nothing is known. The admissions to hospital last week numbered 42, as compared with 65, 36, and 25 in each of the three preceding weeks; the number of patients remaining in the wards has been steadily falling since it stood at 342 on Saturday, Aug. 24th, and was 307 on Saturday last. A few cases have occurred in the Ham districts, but otherwise the home counties seem to be free, and the western and midland registration areas show but little evidence of the disease. Some half-dozen towns in Lancashire continue to record attacks; in the Openshaw portion of the county borough of Manchester 3 fresh cases appeared last week, as well as 1 in Salford; one death occurred in the city also; but Oldham, while having a few cases, was free from fatal attack. In Dublin the cases are few and of a decidedly mild type, since no death has been registered for some weeks; and in the first week of this month only 4 admissions to hospital were reported, together with 6 discharges, leaving 13 acute cases under isolation.

THE PHENYL-HYDRAZIN TEST FOR SUGAR IN URINE.

DR. R. T. WILLIAMSON of Manchester has recently published in brochure form the results of his experience of the value of the phenyl-hydrazin test for sugar in urine for clinical work. He points out that the test may yield crystals from normal urine if the mixture is heated too long, but he has never succeeded in obtaining these crystals when the urine was boiled in a test-tube for two minutes only, a fact which he thinks removes the objection that the test is too sensitive. He proceeds as follows. A test-tube of ordinary size is filled for about half an inch with powdered hydrochlorate of phenyl-hydrazin; then acetate of soda in powder is added for another half-inch. The test-tube is next half filled with urine and boiled over a spirit lamp. By shaking the tube the salts soon dissolve, and after the liquid has reached boiling point the boiling is continued for about two minutes. The tube is then allowed to stand and is finally examined. If sugar is present a yellowish deposit forms at the bottom of the tube, and on microscopical examination this deposit is seen to consist chiefly of beautiful needle-shaped crystals of a bright sulphur-yellow colour. The test can be performed and the characteristic crystals easily obtained even if the urine contains a large quantity of albumin, the crystals of phenyl-glucosazone being easily distinguished under the microscope from the amorphous granules of coagulated albumin. By the manner of proceeding just described no crystals are obtained, it is said, in normal urine. Small crystals, which may be due to glycuronic acid or to minute traces of sugar, are, however, obtained on prolonged heating; but phenyl-hydrazin possesses the one distinct advantage over Fehling's test that it gives no reaction with uric acid, creatinine, or hippuric acid. Some of the disadvantages of the Fehling test to which Dr. Williamson alludes are avoided, we may point out, by the use of ammonia with Fehling's solution, as suggested by Dr. Pavy.

FORMALDEHYDE DISINFECTION BY MEANS OF LAMPS.

FORMALIN or formic aldehyde has been largely employed of late as an antiseptic, and an important application of its properties is its increasing adoption as a preservative for milk, beer, and other liquids. Its employment for this purpose does not appear to be open to any objection, since very minute quantities suffice. It has recently been proposed to prepare this substance by a somewhat novel method which may be conveniently available for disinfecting rooms &c. It is well known that the partial combustion of ordinary alcohol may be effected by means of a previously heated platinum wire. Thus, if a spiral of platinum wire be wound around the wick of an ordinary spirit lamp so that the spiral projects half an inch or so above the top of the wick, combustion continues to go on after the flame has been blown out, the wire remaining incandescent, while the spirit undergoes a change from alcohol into aldehyde. It is an instance, so to speak, of incomplete combustion in which the incomplete product of oxidation, aldehyde, is obtained instead of the complete product, acetic acid. Thus, $C_2H_6O + O = C_2H_4O$ (aldehyde) $+ H_2O$, but $C_2H_6O + 2O = H_2O + C_2H_4O_2$ (acetic acid). It is only necessary to substitute wood spirit for ordinary spirit of wine when, instead of acetic aldehyde, formic aldehyde is obtained. Lamps have been especially constructed with platinum screens for this purpose, and it is suggested that they would afford a convenient means of giving off the vapours of formaldehyde for disinfecting hospital wards, infected dwellings, &c. Since the vapours of formaldehyde have no injurious effect upon furniture and metal fittings, this method may prove a useful precautionary sanitary measure and an important addition to our ordinary means of disinfection. We are not so sure, however, that it can be an economical method, as from the very nature of the process—namely, that of imperfect combustion—the yield of formaldehyde is sure to fall short of theoretical requirements, while loss from volatilisation of unchanged spirit is another factor that must be taken into account.

MEDICAL VACATION NOTES.

(FROM HOLIDAY CORRESPONDENTS.)

I.—NORTH CORNWALL.

THERE are indications that North Cornwall is about to be a favourite holiday resort. And there are many reasons why it should be so. This region (Tintagel and Boscastle) has still the great charm for Londoners of being off the great highway of tourists. The line from Okehampton is a single one, and there are four or five miles to be traversed by coach from Camelford. There are occasional invasions for the day by trippers in carriages, to the embarrassment of the limited commissariat of the one or two hotels and the two or three shops of the place. But the scale of the cliffs and downs makes their presence scarcely felt by the regular visitors, who can vary their walks or drives every day for a month and still feel that there is much to see and interest them. The people themselves are a study, and a pleasant one. There is an air of primitive courtesy about them. The humblest labourer or his children have a civil and kindly salute for every stranger they meet, and in their dealings are reasonable and unexacting. They are not rich, but they are comfortably and contentedly poor. The children are nice-looking and healthy in appearance. They are dressed in taste, with good shoes and stockings, contrasting favourably with what one would see in corresponding districts of other parts of the United Kingdom. Wages are fairly good, about 15*s*. a week. Commodities are few and humble; wants are correspondingly simple. One of the social features of the district is the extreme temperance of the people; public-houses are scarcely to be seen. Teetotalism is common and almost an element in the creed of the natives, who in their way are very religious, with a strong tendency to Nonconforming types of worship, more or less Wesleyan in character, and "Bible-Christian," whatever that may mean. The industries of the district are mostly agriculture and slate-quarrying. Medical men are not in much demand. The two practitioners of the district are well employed and much appreciated. But there is no room for more. The chief charm of the place, of course, is its scenery of cliffs and sea. The castle and its rock, with its historic and prehistoric associations, and the old churches on the westernmost cliffs of this almost westernmost coast looking straight over to

Digitized by Google

Labrador, may be left to the guide-books. The cliffs, dark and steep and high, on a scale scarcely to be equalled in any other part of England, afford infinite "harvests" for "a quiet eye," and at some points a grand view of the Atlantic horizon, with a characteristic coast line of thirty or forty miles. The cliffs are of infinite variety, but all bold and precipitous, befitting the office they serve of breakwaters to the magnificent seas by which they are so splendidly assaulted on the smoothest summer days. They are backed by downs altogether worthy of the sea. These downs are covered with fine grass, heather, gorse, and wild flowers in great variety, affording the amplest field for the botanist, the sketcher, or the mere walker who finds his rest and recreation in the open, undulating hills rising at points to 1000 ft. and with "the chartened winds beating about him." The prevailing winds are south-west, but the warmth is tempered by the sea breeze, which rarely fails one on the cliffs. Among walks so exquisite and so varied it is almost invidious to single out any for special praise; but that to Trebarwith, including Backways, to Boscastle by the cliffs, and a visit to the Rocky Valley at the hour of high tide, and to the Tintagel Willapark, cannot go unmentioned. The visitor is within an hour's drive of the mountains to be ascended, Row Tor and Brown Willy, of the slate quarries of Delabole, &c.

There is only one drawback to the charm and merit of this district considered as a health resort. But it is a serious one. It admits of easy remedy, or would do so if the easy-going, good-natured inhabitants were not too contented with their natural environment. I refer to certain grave sanitary defects, and especially to the want of drainage and of a sufficient and pure water-supply. Drainage is not regulated by any by-laws of the sanitary authority. The district abounds in natural springs, the water from which in its pure state is exquisitely pure and good. Wells are to be found everywhere, almost at every house. The temptation to use these is irresistible, as fetching water from a distance means either trouble or expense. Yet many of them are liable to the most obvious and coarse contamination. Boscastle, I believe, has already selected a source of unobjectionable water and is on the point of receiving it. In Trevena, too, the principal village of Tintagel, the water-supply is for the most part good. But the outlying houses, apart from the larger villages, depend on local wells and springs exposed, as already said, to many sources of filth. Accordingly one is not surprised to learn that in certain houses typhoid fever and diphtheria have asserted themselves with an unpleasant emphasis. The incidence of such outbreaks has been typically vivid in its significance of intensely local causes. They have been sharply limited to a few houses or to those having a connexion with them. As far as I know, they have never affected visitors, but have been confined to the inhabitants who most resist the elementary lessons of public and domestic health. What is almost more discouraging than such occurrences is the inadequate perception of their significance by the inhabitants affected, of the most decent and even religious character, but too ready to attribute to the will of God evils altogether in their own control. In one house, or in connexion with it—that of a leading and most useful inhabitant—as many as seven cases of typhoid fever occurred over a period of years. He was a most active member of the district council and shut his eyes to the lesson of successive cases on or connected with his premises. At last, and quite lately, he himself was attacked. He was then convinced and declared that when he recovered he would see to putting things right. But it was too late. He succumbed, partly from organic complications,—the only fatal case of the series, most or all of which might have been prevented. Such evils could be easily removed with a little more public spirit and local intelligence in regard to the causation of disease. But these are plants of slow growth in sequestered spots like this. The only hope of amendment is in the immediate reform of the sanitary administration. The medical officer of health for Tintagel and Boscastle holds his responsible office at a salary of £12 a year. But the £12 a year is the whole salary for acting as medical officer for seven parishes, with deduction for income-tax &c.—that is to say, at the rate of about 35s. per parish per year. The arrangement is a mockery in all its aspects, disrespectful to the holde rof the office, and inconsistent with public health. It must indefinitely postpone the development of this delightfu district as a health resort. Throughout Cornwall, I believe, the same arrangement holds. What is wanted is the appointment of a medical officer of health for a large district or for the county, excluded from private practice, and with a proper salary. I have every reason to believe that such an arrangement would be approved of by the local practitioners. Every consideration should dispose the inhabitants to acquiesce in such a reform and in the rigid administration of sanitary law. Without these they are liable to the most tragic occurrences of disease in their own homes and cannot hope to see that prosperity of the district as a health resort which would surely come if the evils I have felt it my duty to point out were removed. The great majority of parishes in Cornwall, thirty-one out of thirty-six, have adopted the Notification Acts. But these are only a means to an end, and will of themselves neither isolate nor prevent disease. In the Tintagel and Boscastle district there is neither an isolation hospital nor disinfecting apparatus.

II.—IN THE TYROL.

THE Tyrol may be conveniently approached either by way of Munich and Innsbruck, or through Constance and the Arlberg Tunnel, or from Venice. For various reasons unnecessary to specify we chose the third of these routes, and after a rapid journey found ourselves once more in the mysterious City of the Lagoons. Venice may be fairly reckoned among those few things in the world which are absolutely unique. It is unique in its situation, unique in its history, and unique in its vast accumulation of artistic wealth. It is not, indeed, unique in its fate, for other great cities have suffered an even greater fall. But that fate is sufficiently pathetic. Venice is now a second-rate provincial town of Italy, with an empty harbour and a mendicant population. Yet

"Once did she hold the gorgeous East in fee."

Time was when she "sate in state, throned on her hundred isles." Now she is a discrowned queen. But her charm remains unaltered, if not, indeed, deepened by the irony of history. The Doge's palace stands erect in all its splendour, and the masterpieces of Tintoretto and Paul Veronese still look down from its walls, recalling the regal past and challenging comparisons with the present. St. Mark's is still there, glittering within and without with the spoils of the East and the West, and bearing testimony to the pomp and magnificence, if not to the piety, of the generations that are gone. The tides of the Adriatic still flow under the Rialto, and one thinks of Antonio and Shylock, of Desdemona and the Moor, and feels that the creations of the mighty magician are hardly less substantial than the warriors and statesmen who sleep their last sleep in the Frari or the Church of San Giovanni e Paolo. But it is on the Lagoons that one realises most fully the special charm of Venice. To drift in a gondola in view of St. Theodore and the Lion of St. Mark, while a light breeze is setting in from the Adriatic and the fishing boats are coming up from Malamocco, to listen to the chime of many bells across the still waters, and to watch the declining sun making a glory in the West—this is sufficient to stir the most sluggish blood and to fire the feeblest imagination. Although it was August we found the temperature by no means oppressive. The breeze from the sea seldom failed, the constant wash of the tide seemed to preserve freshness and purity in the canals even in the dog-days, and the charming sea-bathing at the Lido was compensation for an occasional hot hour or an infrequent mosquito bite. Our countrymen were conspicuous by their absence, but there were many Italian visitors and some Americans. At night the Piazza of St. Mark's presented a gay appearance, the whole population turning out to enjoy the evening cool to the strains of excellent military music. Venice is indeed the paradise of the pleasure-seeker. Her silent waterways, where the only sounds are the chimes of bells or the warning calls of the gondoliers, her majestic but half-empty churches, her palaces and galleries, her petty industries and innumerable beggars—all these seem to make existence a mirage, work a delusion, and energy an anachronism. "It is impossible to take life seriously here," said a friend to the writer, and truly in Venice Anglo-Saxon vitality and progressiveness seem a sort of solecism. To enjoy the luxurious present and to dream over the magnificent past—this seems natural and fitting in Venice, and the holidaying tourist in search of rest and

Digitized by Google

refreshment will find few places so well adapted for his purpose.

Leaving Venice by the evening train we found ourselves traversing a rich plain covered with vines and mulberries, orange and lemon trees, maize and olives. It is afflicting to think that poverty should be rife among a people to whom Nature has been so lavish in her gifts. With a proper agriculture and a wise Government, Italy should be one of the richest and most prosperous of countries. Late at night we arrived at Belluno, at the foot of the Alps and near the entrance to the Val d'Ampezzo, by which we proposed to enter the Tyrol. On the following morning we started by diligence for the long drive to Cortina in the Dolomite region. The weather was magnificent, and the scenery soon became Alpine in character. We were ascending the picturesque bed of the Piave, now in these August heats a tiny stream creeping over white sands towards the Adriatic, but showing traces all round of winter turbulence and widespread devastation. On either hand arose Alpine heights dark with pine and clothed with rich forests of birch and castagna. In a few hours the first peaks of the Dolomites began to raise their quaint pinnacles and minarets above the surrounding mountains, announcing our approach to a region of remarkable geological formation and of exceptional interest. In the afternoon we halted for a brief space in the little village of Pievè-di-Cadore, the birthplace of Titian, which occupies a magnificent situation high above the steep valley of the Piave. A statue of the great painter stands in the little piazzi, in one of the houses of which he first saw the light. Ruskin's persistent depreciation of Titian is puzzling to the tourist in Italy who can boast of nothing more than an amateur's knowledge of art. To the unsophisticated eye his paintings seem to possess a felicity of design, a grace of arrangement, and a richness of colouring hardly surpassed by Raphael or Rembrandt. That he does not touch the supreme heights of inspiration and that his pictures lack the special note of sanctity may be admitted, but what great merits remain, what power, what grace, what versatility. The facts that Titian is a universal favourite and that his masterpieces are found in every great collection are surely decisive proofs of his true greatness. He has deeply touched—*pace* Ruskin—the general heart of humanity. In art, as in most things, it remains true that "everybody is wiser than anybody"—*Securus judicat orbis terrarum*. Late at night we reached Cortina.

Cortina is grandly placed in the centre of the Dolomite country. The monarchs of the Dolomites stand around—Tofana, Cristallo, and Sorapiss—all fine peaks from 10,000 to 11,000 feet in height. These mountains will not compare in height or in expanse of snowfield and glacier with the giants of the Bernese Oberland—the Jungfrau, the Eiger, and the Fuisteraarhorn—or with the still loftier summits of the Pennine Alps, but they have a special character and a peculiar beauty of their own. They are composed chiefly of magnesian limestone, and they are remarkable for their jagged outline and serrated summits. One of the most noteworthy of these is the Drei Zinnen, not far from Cortina, which resemble three vast cromlechs piled heavenwards. These mountains are difficult of access and present to the mountaineer all the worst problems of rock climbing in their acutest form. But they have all been overcome, for in these days nothing daunts the climber and nothing stimulates his ambition so much as an untrodden and presumably inaccessible peak. We did some modest climbing among these Dolomite Alps, nothing heroic or dangerous, but sufficient to get a glimpse of their beauties and to form some estimate of their dangers. One is struck with the contrast between the bare and precipitous peaks and the smiling and luxurious valleys at their base. In these southern regions of the Tyrol the general aspect is that of Italy rather than Austria or Switzerland. The varied colour and rich luxuriance of the valleys that slope up from the plain of Italy, the soft air and azure sky, the complexion and tongue of the inhabitants—all speak of the south. Although in Austria, we are still to the south of one of Nature's physical and moral watersheds. Only the gaunt peaks of the Dolomites remind us that we are in a region geologically *sui generis*, though the Government is Austrian and the tongue Italian. On our return from one of our excursions at Cortina we enjoyed the sensation of a heavy Alpine thunderstorm. The morning had been fine and hot, but lowering, and about four o'clock, when we were tramping on foot from Schluderbach towards Cortina, the sky suddenly darkened, there was an ominous muffled roar towards the south, and in a few minutes the storm burst furiously over us. The lightning flashed incessantly, now in magnificent sheets, again in ghastly zigzags; the thunder hurtled and crashed and reverberated, awakening symphonies of Titanic music amidst the rocky fastnesses of Monte Cristallo and the Croda Rossa; the rain descended in solid cataracts. There was no shelter, so we trudged on, not without some inward qualms, but determined not to show the white feather. Nearer and more fierce grew the tumult, until at last with one final explosion, as if all the ironclads of the world had poured a broadside into all the china-shops extant on this planet, the storm seemed to have exhausted its violence and retreated with angry rumblings towards the north. We reached our hotel tired and wet to the skin, but uninjured.

From Cortina we went by a somewhat circuitous route to Meran, and found that charming health resort entirely out of season and dull to a degree. As a matter of fact, we had arrived at quite the slackest of the slack-water period. Meran has a grape cure in autumn, a milk and whey cure in spring, and is a favourite sanatorium for pulmonary invalids in winter, but in the height of summer it is deserted. The town is charmingly situated amid vine-clad mountains, and shelter is excellent on all sides except towards the south, where the broad valley of the Adige opens up towards Italy. The climate is sunny and dry and on the whole mild, but the winters are cold as compared with those of the Riviera, Malaga, or Palermo. The elevation is 1050 feet, and the climatic conditions may be loosely reckoned as in some sense resembling those of Montreux. It is, perhaps, hardly fair for one who has no practical experience of the grape cure or the milk cure to offer any criticism upon those methods of treatment, but it is a little difficult to take either one or the other quite *au grand sérieux*. That for many persons who have eaten and drunk not wisely but too well to live for a few weeks chiefly on grapes or whey might be most desirable is true enough, but this is hardly serious scientific treatment As a winter resort for the phthisical Meran is well worth attention, but its merits are, perhaps, sufficiently well known. It is a good example of the sheltered, sunny, dry, somewhat elevated, and moderately tonic resort. Cases that find Davos or St. Moritz too severe might do well at Meran. The surroundings are most attractive and the accommodation excellent.

From Meran we pushed on for the Great Ortler, the great goal and object of ambition to all tourists with mountaineering tastes who visit the Tyrol. This superb mountain is one long day's drive from Meran, and mountaineers may elect to stay either at Sulden or at Trafoi on the Stelvio route. We chose the latter and found comfortable quarters at the Hotel de la Poste. Soon after arrival we completed arrangements with two Tyrolese guides to start on the following afternoon for the ascent of the Great Ortler. This mountain, which is just under 13,000 ft. in height, is one of medium difficulty and danger. While free from avalanches and almost free from falling stones, and presenting no special feature of peril, it is not a mountain for the novice in climbing. It is steep almost throughout, much of the climbing consists of steps cut in a precipitous ice wall, and several of the *arêtes* call for a steady head and practised nerves. But for the mountaineering expert, accompanied by good guides, the Great Ortler is an easy mountain. We left our hotel at Trafoi about 2.30 o'clock in the afternoon, and, crossing the brawling Trafoierbach at once, began the steep ascent through pine woods. It was an August afternoon, hot and sultry, and heavy masses of clouds wreathed themselves round the higher peaks, rendering the meteorological prospect somewhat doubtful; but our Tyrolese guides were sanguine on this score, so we braced ourselves for the considerable effort before us. Our intention was to go on the first evening only so far as the Payerhütte, a hut erected on the Great Ortler by the Austrian Alpine Club at an elevation of about 10,000 ft. The first two or three hours of an ascent are in some respects the most trying. One has not quite escaped from the hot air of the valleys, and the heart and lungs have not fully accommodated themselves to the altered mechanism rendered necessary by the increasing rarefaction of the air and the severe muscular efforts. It is a cardinal rule of mountaineering to proceed very deliberately at first, and never to allow palpitation or dyspnœa to get the mastery. The guides plod on usually in silence, most watchful at all dangerous points and ready and expert in giving the needful aid. After nearly two hours of steep and continuous climbing we emerged from the pine

Digitized by Google

forests and entered upon a long track of stone and rock. Already we had attained a considerable elevation, and the vistas became every moment more extensive and impressive. At a prodigious depth below our feet lay our hotel at Trafoi, and so steep was the ascent that it seemed almost as if a stone might be dropped upon it. In another hour, at an elevation of about 9000 ft., we first touched snow and began the passage of the first glacier of the Great Ortler. This safely surmounted, a short reach of severe rock climbing brought us to the Payerhütte about nightfall. Here we found a numerous party of Austrians and Tyrolese guides assembling with a view to the ascent next morning to the summit. Great was the anxiety about the weather. The night closed in ominously enough: the sun sank luridly behind great banks of clouds in the west, shooting out a few parting rays to illumine the peaks and snowfields of the Tyrol, great masses of mist began to surge up from the valleys, and we retired to our narrow quarters in the hut in rather a desponding mood. Next morning we were on foot shortly after 5 o'clock, and were agreeably surprised to find that the weather prospects, though still doubtful, were encouraging. The prospect from the Payerhütte at this hour was most imposing. The sun was rising over the Eastern Tyrol, and peak after peak was struck by his brilliant beams. The view embraced the Ortler Alps, most of the Tyrol, the Bernina chain, the Engadine region, and the highlands of Bavaria. The air was keen and crisp and the thermometer at the door of the hut marked 5° below Zero (C.). After some light refreshment we were roped to our guides, and the last and most difficult stage of the ascent began. From the Payerhütte to the summit of the Ortler is a steep ascent of 3000 ft. over snowfield and glacier. The guides go in front, cutting steps in the ice and snow as may be needful, and the mountaineer follows cautiously in the rear. There are many places where a serious slip would be immediately fatal, but with great care and sufficient physique and nerve the dangers are probably moderate. The panorama was extensive and magnificent, but at above 11,000 or 12,000 ft. the distant views became indistinct and one was conscious only of a vast expanse of mountain and valley and distant plain. We reached the summit at 9 o'clock, but found it in cloud. After a short rest and some refreshment we began the descent, and reached our hotel in Trafoi at 2 o'clock in the afternoon without mishap. We drank some milk and brandy and went straight to bed. After a short sleep we rose and dined, and we can commend this plan to mountaineers. To eat a full meal when in a state of extreme fatigue is a great blunder. Our experience also inclines us to the view that one should be most sparing in eating and drinking during the actual ascent, and that alcohol should either be avoided or taken in great moderation; cold tea is refreshing and safe; on the other hand, when the fatigues of the ascent and descent are over alcohol is invaluable as a restorative.

From Trafoi we proceeded to Laudeck by the beautiful Frustermünz Pass, the Great Ortler grandly dominating the landscape for many miles; from Laudeck to charming Innsbrück, and thence to England by Munich and the Rhine. The Tyrol forms an almost ideal holiday resort. The scenery is in a high degree varied, interesting, and beautiful; the accommodation is, on the whole, excellent and cheap; while the people are frank, intelligent, and obliging. True, the Tyrolese *Jodel* has to be endured, but where is the rose that is quite thornless?

REPORT OF THE COMMISSIONERS IN LUNACY FOR SCOTLAND FOR THE YEAR 1894.

ON Jan. 1st, 1895, there were 13,852 insane persons under official cognisance in Scotland. Of these, 2138 were maintained from private sources, 11,660 by parochial rates, and 54 at the expense of the State. With regard to the distribution of the insane in the different classes of establishments and in private dwellings, the following differences appear in the manner of distribution of registered lunatics at Jan. 1st, 1895, when compared with what it was at Jan. 1st, 1894. In royal and district asylums there is an increase of 87 private patients and an increase of 222 pauper patients. In private asylums there is a decrease of 6 patients. In parochial asylums there is an increase of 112 pauper patients. In lunatic wards of poorhouses there is an increase of 7 pauper patients. In private dwellings there is an increase of 5 private patients and an increase of 112 pauper patients. Tables I., II., and III. (Appendix A) show the number of patients, the manner of their disposal, and their proportion to population and to ordinary pauperism at Jan. 1st, 1895, as compared with previous years.

The general results during 1894, as compared with 1893, are, in regard to registered lunatics, as follows: 1. There was a total increase of 539, of whom 87 were private patients and 452 were pauper patients. 2. Of the total increase of 539, the increased number in establishments was 422 and in private dwellings 117. 3. Of the increased number of 422 in establishments, 82 were private patients and 340 were pauper patients. As the average annual increase in the number of private patients in establishments in the five years 1891–95 has been 49 and of pauper patients 206, the increase in the number both of private and of pauper patients in establishments during the last year has been considerably above the average annual increase of the quinquenniad. 4. All pauper lunatics in establishments continue to be provided for in institutions of a public character.

The increase of 452 in the number of pauper patients is stated to be the largest that has taken place in any one year since the Board of Commissioners entered on its functions in 1858. Mention is made of the localities in which the increase has chiefly occurred, and it appears that of the total year's increase 56 per cent. were contributed by the following counties, all of which have large urban centres of population: Aberdeen, Edinburgh, Forfar, Lanark, and Renfrew; 15 per cent. by counties having smaller active industrial centres, either towns or rural mining districts—namely, Ayr, Dumbarton, Linlithgow, Selkirk, and Stirling; and 18 per cent. by three large and purely Highland counties: Argyll, Inverness, and Ross. The Commissioners point out, however, that in the first two groups of counties the population is increasing, and that the increase in the number of pauper lunatics is therefore to some extent, though not to a large extent, due to increase of population. But in the three Highland counties named the population is falling, and the increased numbers of pauper lunatics in these counties which have come upon the register must, therefore, be ascribed wholly to causes other than increase of population. The Commissioners, in seeking an explanation of this increase in the Highland counties, refer to the change in social conditions and views of life even in these remote parts, where insane persons now placed on the register would formerly have been kept at home, and where the inhabitants are now ready to acquiesce in or even to urge their removal to asylums. Again, where they do not remove insane members of the community to asylums there is shown an increasing readiness on the part of relatives to claim the State contribution in aid, registration thereafter becoming a necessity. The table of admissions discloses the facts—(1) that the number of private patients admitted during last year was 515, being 16 less than during the preceding year and 19 less than the average for the quinquenniad 1890–94; and (2) that the number of pauper patients admitted was 2661, being 148 more than the number during the preceding year and 233 more than the average for the quinquenniad 1890–94.

There were 197 private patients discharged recovered during the year, and this number was 27 below the number for 1893 and 13 below the average for the five years 1890–94. The number of pauper patients discharged recovered was 1130, or 55 below the number for the preceding year and 58 above the average for the five years 1890–94. The number of private patients who died in establishments during 1894 was 106, which is 38 less than in 1893 and 27 less than the average of the five years 1890–94. The number of pauper patients who died was 712, which is 11 less than in 1893 and 7 below the average of the five years 1890–94. With reference to the number of patients liberated on probation the Commissioners state that of the 4010 patients so liberated since 1862 801 were replaced before the expiry of the period of probation, but they add that they "continue to be of opinion that in some establishments a more frequent application of the probationary discharge to patients whose fitness for residence in private dwellings may be uncertain would probably lead to a larger number of permanent discharges than takes place at present." This is very true; but we always feel that unless the surroundings into which the patient is discharged are well adapted for his proper care and supervision the risk of premature discharge is one that ought not lightly to be run.

The whole number of escapes during 1894 was 236. Of

Digitized by Google

these, 131 were brought back within twenty-four hours, 63 within a week, and 17 after a week; 25 were not brought back during the currency of the Sheriff's order or the certificate of emergency on the authority of which they had been detained. Of the 25 patients not brought back 4 were removed from the asylum registers as recovered, 10 as relieved, 7 as not improved, 2 were permitted to remain out on pass or probation, 1 was drowned, and 1 committed suicide by hanging. The two latter occurrences are referred to under the heading "Accidents in Asylums." The following statement shows the comparative expenditure for pauper lunatics since the quinquenniad 1859–63.

—	Annual expenditure per patient. In asylums including institutions for imbecile children.	In lunatic wards of poorhouses with restricted licences.	In private dwellings.	Total.
	£ s. d.	£ s. d.	£ s. d.	£ s. d.
1859–1863	23 17 3	17 11 7	8 13 1	18 11 6
1864–1868	24 8 4	19 13 1	9 15 11	20 6 1
1869–1873	25 0 1	17 17 4	11 1 9	21 16 6
1874–1879	26 19 5	20 15 3	12 13 11	24 6 5
1880–1884	26 7 4	19 14 8	14 2 1	24 5 5
1885–1889	25 16 6	19 1 0	15 6 7	23 12 5
1890–1894	25 1 10	19 1 1	16 0 5	23 5 3

The Commissioners speak in very favourable terms of the general condition and management of establishments for the insane. The Deputy Commissioner, Dr. Lawson, reports as follows on patients in private dwellings. "Another year devoted to the inspection and supervision of insane persons living under domestic care in Scotland confirms in my mind two opinions which I have formerly expressed. The first is that the method of retaining or recalling from institutions suitable insane persons to share in the benefits of private life has a rational justification in the social instinct from which springs the desire for a specific home and a circle of habitual associates. The second is that prolonged experience shows that in Scotland a large percentage of those who are registered as lunatics can, from the first or at a later stage of their malady, be provided for and treated in private dwellings in a manner which yields results satisfactory to themselves, and which causes little, if any, departure from the current of daily life of the families and the communities in which they are placed. In short, the system of providing in private dwellings for properly chosen patients has the sanction of an elementary instinct; it acts as a boon to many of the insane as well as to the ratepayers, and it causes no appreciable interference with either the performance of the duties or the enjoyment of the privileges of the general public."

The Commissioners record their great regret at the retirement of Sir Arthur Mitchell from the board, and they pay a well-deserved tribute to the leading part that he has taken in the institution and development of the system of lunacy administration as it now exists in Scotland.

THE MANCHESTER MEDICAL CRICKET CLUB.

LOVERS of the national game will be gratified to hear that the Manchester Medical Cricket Club has prospered during the season which has just closed. It has about 120 members, medical men and students, and is in the sixth year of its existence as a regularly constituted club with president, vice-presidents, committees, &c. Its history dates back for about eight years, during the first two of which several matches were played, but in these early days its programme was less ambitious than it now is. The club's expansion since it has been conducted on the present lines is very marked, and affords a happy illustration of the readiness of medical men to coöperate with one another in availing themselves of opportunities for healthful recreation and the cultivation of social amenities. Of late years as many as eight or ten matches have been played in the course of a season against such opponents as the Clergy, the Law, Cheadle Asylum, Prestwich Asylum, and the Liverpool Medicals, to which must be added Past *versus* Present matches. The contest with the Liverpool Medicals has become the event of the year, and takes place alternately at Old Trafford (Manchester) and Aigburth (Liverpool). This year it was played on the picturesque ground at Aigburth in splendid weather and in the presence of a large gathering of medical men and their friends. The annual subscription to the club is five shillings for members of the profession who are players and half a crown for those who are not players and for students. Most of the playing members belong also to the county or local clubs and take part in matches against elevens from all parts of Lancashire, Cheshire, and Derbyshire. There is, therefore, but little inconvenience occasioned by the fact that the club has not yet acquired a ground. The Manchester clergy can make up a strong eleven, and their contest with those of Liverpool is generally very keen. The formation of medical cricket clubs in the larger centres of population is an excellent idea and a precedent worthy of imitation wherever circumstances permit. Perhaps some day inter-county medical matches may be played. The relaxation and change of scene provided by occasional visits to the cricket ground are welcome interruptions of the daily routine of practice, and, in addition to benefiting the health and the temper, they afford invaluable opportunities for the commencement of acquaintanceships and the promotion of general good feeling. Moreover, there is no dearth of capable players in our ranks, for the elevens engaged in county matches sometimes include members of our profession who, though far from approaching the exploits of the champion medical cricketer, nevertheless contrive to do good work for their sides. Our cricket-playing colleagues in Manchester, Liverpool, and Preston[1] have our hearty good wishes, and we sincerely hope that their respective clubs may long continue to flourish.

POISONING BY SOUP AT WOLVERHAMPTON.

As our readers are aware,[2] several cases of illness and one death unhappily followed the use of soup distributed last August from the vicarage of Heath Town. At the inquest, which was concluded on Sept. 16th, the vicar's cook stated that on Thursday, Aug. 8th, she prepared the soup for the usual Friday distribution. The ingredients were a portion of a roast sirloin of beef cooked on the previous Sunday, some fresh loin of mutton, and part of a chicken that had been boiled on Thursday for the family dinner. These were cut into small pieces and boiled in an ordinary iron saucepan with the broth left after the cooking of the chicken. When the soup was ready the saucepan with its contents was set to cool on the stone floor of the adjoining scullery, and as the family were going from home it remained there in the uncovered saucepan until Saturday morning, when the distribution took place. She tasted it on Saturday and found it to be perfectly sweet and not fermented at all; no colouring was used in it. The scullery sink had an open pipe to the drain outside. The deceased woman, who was fifty-five years of age and married, warmed some of the soup at home in a tin saucepan, and it was consumed by herself and husband and their son and grandson. The same evening these four persons and five others, relatives and neighbours residing in the same street, who also had some of the soup, were seized with serious illness, purging, and vomiting. A medical man who was called in on Monday, Aug. 12th, found the deceased, her husband, her son, and four other persons suffering from vomiting, purging, and abdominal pains. He was unable to obtain a sample of the soup. The deceased expired on Aug. 17th, and the house physician at the Wolverhampton General Hospital, who made the post-mortem examination on Aug. 19th, said that the body was then in a high state of putrefaction, the face and hands

[2] THE LANCET, Aug. 24th, 1895, p. 460.

Digitized by Google

being black, and he was unable to form any conclusion as to the cause of death. He sealed up the stomach, liver, kidneys, and spleen in jars. Two witnesses, mother and son, who received some of the soup from the vicarage, stated that it was very nice, and they experienced no ill-effects. Dr. A. P. Luff, lecturer on Medical Jurisprudence at St. Mary's Hospital, London, said that the viscera were forwarded to him on Aug. 23rd, and were free from mineral or vegetable poisons. The stomach and liver contained small amounts of ptomaines, but he could not say whether this was derived from the soup or from the decomposition of the viscera independently of the soup. Assuming that the poisonous matter was in the soup, the immunity of those witnesses who suffered no ill effects might, perhaps, be due to their having made it hotter than the other families did. The verdict was, "Death from syncope, the result of ptomaine poisoning, such poisoning being accidental."

CHOLERA.

IN referring last week to the cholera prospects of this season we briefly summarised the facts so far as they were known regarding the prevalence of this disease at the present time. There has no doubt been a revitalisation or recrudescence of cholera in various countries and places abroad where the epidemic had already prevailed during previous years, but the renewed activity has happily not been manifested on any large scale. The occurrence of some suspicious cases at Grimsby naturally gave rise to some fears when viewed in connexion with the past history of that town. These were, however, soon dispelled when the results of the bacteriological examination became known and it was also found that the disease showed no signs of spreading.

At the present time, in addition to the officially reported prevalence of cholera in Russia and the existence of the disease in other countries bordering on the Russian frontier, cholera still seems to be prevailing in Tangier, where it broke out a short time ago. Six fresh cases and 9 deaths were registered at Tangier on the 17th inst., and the existing restrictions imposed by the Gibraltar Board of Health on arrivals from that place are maintained, a short quarantine having also been imposed upon arrivals from Ceuta and other ports on the Moorish coast. A serious cholera outbreak is reported at Algiers. The deaths from that disease are stated to have been forty-three on the 17th inst. With regard to the alleged outbreak of cholera at Honolulu no further intelligence has been received, nor has any additional news reached us from the East regarding the epidemic in China and Japan.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Nottingham Urban Sanitary Authority.—As an instance of the importance of measles as a factor in mortal statistics, Dr. Philip Boobbyer reports that during 1894 this disease caused more deaths than did scarlet fever, enteric fever, and diphtheria combined. Four schools were closed during the year under review in an attempt to check the spread of measles, but no good results from the action were, Dr. Boobbyer reports, apparent. The system adopted at Nottingham of paying for the persons exposed to small-pox during a period of sixteen days' quarantine has been found to work extremely well, and it has curtailed considerably the spread of the disease. In the matter of scarlet fever Dr. Boobbyer, as in former years, contrasts the hospital with the home fatality rate, that for the former being 2·7 per cent. and that for the latter 10·4. While admitting that part of the difference may be due to the fact that very severe cases are kept at home, Dr. Boobbyer considers that the chief factor has been the careful nursing provided at the hospital, together with the confinement to bed of all patients for a minimum period of three weeks. The meaning of the accompanying table is sufficiently obvious, and it will be of a special interest to our readers since we have on former occasions reproduced similar tables from Dr. Boobbyer's reports. The most noticeable feature in the figures is, perhaps, the high fatality rate amongst cases infected by those discharged from hospital, and in whom it might be supposed the power of infectivity was, if present at all, but feebly so. Dr. Boobbyer has noticed this point for some years past, and its explanation is by no means obvious. It may, perhaps, be that recurrent discharges from the nasal and oral passages of otherwise non-infective patients may possess a high degree of virulence and contain a septic element in addition to the specific element.

Class of cases.	Number of cases.	Percentage of cases.	Number of deaths.	Deaths per cent. of cases.	Total death-rate per cent.
Hospital cases—					
(*a*) Primary	771	66 per cent. of all cases notified	17	2·2	
(*b*) Secondary in houses from which (*a*) came within 21 days of their removal	110	13·5 per cent. additional to (*a*)	4	3·6	2·7
(*c*) Secondary after return home from hospital within 21 days of return... ...	41	4·5 per cent. additional to (*a*) and (*b*)	4	9·7	
Home cases—					
(*a*) Primary	170	14·6 per cent. of all notified cases	16	9·4	10·4
(*b*) Secondary during progress of case at home...	60	35 per cent. additional to (*a*)	8	13·3	

The Nottingham mortuary is not as highly appreciated by the public as such a building should be, but the fact that in this case it is situated in the immediate proximity of a refuse depôt is certainly a sufficient explanation of its unpopularity. From a material standpoint the locality is, perhaps, a fitting one, but a sanitary authority which neglects sentiment as a factor in human affairs must not wonder if their efforts are sometimes not appreciated. In the absence of a public abattoir efficient supervision of the meat-supply is not, Dr. Boobbyer remarks, possible, and as illustrating this point he refers to the case of Edinburgh, a town not much larger than Nottingham, but in which the amount of butcher's meat seized in one month frequently exceeds that seized during the whole year in Nottingham. During 1894 there were condemned in Nottingham 2057 stones of fish and 249 stones of "shell-fish"; of the latter 192 stones were mussels.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6156 births and 3917 deaths were registered during the week ending Sept. 14th. The annual rate of mortality in these towns, which had been 19·9 per 1000 in each of the three preceding weeks, declined again last week to 19·3. In London the rate was 15·4 per 1000, while it averaged 22·0 in the thirty-two provincial towns. The lowest rates in these towns were 11·7 in Plymouth, 13·1 in Norwich, 13·6 in Croydon and in Nottingham, and 13·9 in Bristol; the highest rates were 30·0 in Manchester, 30·8 in Hull, 32·7 in Blackburn, 33·5 in Burnley, and 37·5 in Sunderland. The 3917 deaths included 991 which were referred to the principal zymotic diseases, against 1072 and 1071 in the two preceding weeks; of these, 706 resulted from diarrhœa, 75 from diphtheria, 60 from whooping-cough, 58 from "fever" (principally enteric), 49 from measles, 40 from scarlet fever, and 3 from small-pox. The lowest death-rates from these diseases were recorded in Plymouth, Huddersfield, Swansea, and London, and the highest rates in Bolton, Burnley, Blackburn, Hull, and Sunderland. The greatest mortality from measles occurred in Blackburn; from whooping-cough in Norwich, Birkenhead, Bolton, Burnley, and Bradford; from "fever" in Sunderland; and from diarrhœa in Blackburn, Manchester, Bolton, Burnley,

Digitized by Google

Hull, and Sunderland. The 75 deaths from diphtheria included 55 in London, 5 in West Ham, 2 in Birmingham, and 2 in Burnley. Two fatal cases of small-pox were registered in London and 1 in Manchester, but not one in any other of the thirty-three large towns. There were 307 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 14th inst., against 342, 340, and 323 at the end of the three preceding weeks; 42 new cases were admitted during the week, against 65, 36, and 25 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2674, against 2507, 2512, and 2600 on the three preceding Saturdays; 365 new cases were admitted during the week, against 306, 264, and 336 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 102 and 134 in the two preceding weeks, declined again to 122 last week, and were 46 below the corrected average. The causes of 49, or 1·3 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Bristol, Leicester, Nottingham, Bradford, Leeds, and in ten other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Wolverhampton, and Norwich.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had increased in the three preceding weeks from 16·6 to 17·5 per 1000, declined again to 16·9 during the week ending Sept. 14th, and was 2·4 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·7 in Perth and 14·9 in Leith to 18·5 in Dundee and 20·3 in Paisley. The 489 deaths in these towns included 61 which were referred to diarrhœa, 11 to whooping-cough, 9 to "fever," 5 to diphtheria, 4 to scarlet fever, and not one either to small-pox or measles. In all, 90 deaths resulted from these principal zymotic diseases, against 118 and 105 in the two preceding weeks. These 90 deaths were equal to an annual rate of 3·1 per 1000, which was 1·8 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had been 78 and 74 in the two preceding weeks, further declined to 61 last week, of which 20 occurred in Glasgow, 10 in Edinburgh, and 8 in Dundee. The 11 deaths from whooping-cough showed a decline of 4 from the number in the preceding week, and included 8 in Glasgow. The deaths referred to different forms of "fever," which had been 10 and 4 in the two preceding weeks, rose again to 9 last week, of which 6 occurred in Glasgow. The 5 fatal cases of diphtheria exceeded the numbers recorded in recent weeks, and included 2 in Glasgow and 2 in Edinburgh. The deaths from scarlet fever, which had been 8 in each of the three preceding weeks, declined to 4 last week. The deaths referred to diseases of the respiratory organs in these towns, which had been 54 and 56 in the two preceding weeks, were 52 last week, and were 15 below the number in the corresponding week of last year. The causes of 26, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 23·6 and 22·2 per 1000 in the two preceding weeks, rose again to 25·4 during the week ending Sept. 14th. During the past eleven weeks of the current quarter the death-rate in the city has averaged 23·4 per 1000, the rate during the same period being 18·9 in London and 16·5 in Edinburgh. The 170 deaths registered in Dublin during the week under notice showed an increase of 21 upon the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 20 and 13 in the two preceding weeks; of these, 12 resulted from diarrhœa, 4 from "fever," 3 from whooping-cough, 1 from small-pox, 1 from scarlet fever, but not one from measles or diphtheria. These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 2·9 in both London and Edinburgh. The fatal cases of diarrhœa, which had been 12 and 8 in the two preceding weeks, rose to 12 last week. The deaths referred to different forms of "fever," which had been 5 and 1 in the two preceding weeks, rose again to 4 last week. The fatal case of small-pox was the first recorded within the city during the past four weeks. The 170 deaths in Dublin last week included 43 of infants under one year of age, and 36 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded the numbers recorded in the preceding week. One inquest case and 4 deaths from violence were registered; and 45, or more than a fourth, of the deaths occurred in public institutions. The causes of 16, or more than 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

THE following officers have embarked in the *Britannia* for service in India:—Surgeon-Lieutenant-Colonel Brown, Surgeon-Major Lane, and Surgeon-Captain Durrant. The following officers are under orders to leave India at an early date for home:—Surgeon-Lieutenant-Colonel Blennerhasset and Surgeon-Major Smythe. Surgeon-Major Johnstone has embarked for India in the *Victoria*. Surgeon-Lieutenant Vaughan Williams has been transferred to Fermoy.

INDIA AND THE INDIAN MEDICAL SERVICES.

The Queen has approved of the following promotion in the Indian Medical Service:—*Bengal Medical Establishment:* To be Brigade-Surgeon-Lieutenant-Colonel: Surgeon-Lieutenant-Colonel Charles John Walford Meadows (dated April 1st, 1895).

NAVAL MEDICAL SERVICE.

The following appointments are announced:—Surgeons: A. E. Weightman to Haslar Hospital; F. J. Lilly to the *Katoomba;* W. A. Whitelegge to the Royal Marine Division, Portsmouth; W. J. Colborne to the *Icarus;* S. H. Youel to the *Ruby;* and E. C. Cridland to Devonport Dockyard. Surgeon and Agent: W. E. Dawson at Walton-on-the-Naze.

VOLUNTEER CORPS.

Artillery: 2nd Northumberland (Percy) Western Division, Royal Artillery: Surgeon-Lieutenant J. S. Forrest to be Surgeon-Captain. 4th West Riding of Yorkshire (Western Division, Royal Artillery): James Black Milne, M.B., to be Surgeon-Lieutenant. *Rifle:* 6th Volunteer Battalion the Royal Scots (Lothian Regiment): Surgeon-Lieutenant J. Anderson, M.B., to be Surgeon-Captain.

ENTERIC FEVER IN INDIAN CANTONMENTS.

We are extremely glad to learn that the sources of enteric fever in India are engaging the attention of Mr. Hankin, the energetic and able bacteriologist to the Government of the North-Western Provinces, whose labours in the cause of scientific hygiene and pathology are deserving of great praise. The theory held in Europe and this country of the dependence of enteric fever on a specific agent intimately associated with fæcal contamination of water, milk, soil, or air and with the presence of the typhoid bacillus discovered by Eberth and Gaffky rests upon a large and repeated number of observations, the cumulative effect of which amounts to very strong evidence. While it is admitted, however, that outbreaks of this fever in our Indian cantonments are frequently traceable to and acknowledge the same causes that they do in England, it is contended by many observers that we have not by any means exhausted our knowledge of the causation of enteric fever in India, and that the difficulties in the way of explaining the prevalence of the disease in that country are considerably greater than are commonly realised. Mr. Hankin says that the general excellence of sanitary arrangements in cantonments appears to him to make it improbable that enteric fever is, as a rule, due to any of the hitherto recognised sources of infection. The questions that have now to be determined are whether all the enteric fever of India is associated with the presence of a specific pathogenic bacillus, how that bacillus gains an entrance into the body, and what are the conditions of environment most favourable to its growth and spread. What we want is a systematically and carefully conducted series of observations by a skilled and impartial investigator, and Mr. Hankin can render no greater service to the cause of humanity and science than by devoting his best labours to the subject.

REPUTED REMEDIES FOR SNAKE-BITE.

From time to time announcements are made with more or less confidence that an antidote for snake-bite has at last been discovered, but the efficacy of one and all fails to be established. The Anglo-Indian papers state that Dr. D. D. Cunningham of Calcutta has just published the results of an elaborate series of experiments which he has been conducting with the view of testing the claims of various reputed antidotes, but these results have proved disappointing, for the remedies have all been found to be utterly inefficacious, and a true antidote has yet to be discovered. It is said that Dr. Cunningham has demonstrated that a non-venomous snake, such as the dhamin, may be immune to the poison, thus raising a serious obstacle to the theory of auto-inoculation. It will be remembered that, acting on the hypothesis originally started by Surgeon-Major Waddell—viz., that venomous snakes are autotoxic—Professor Fraser of Edinburgh has been conducting a series of experiments to find an antidote by inoculation with prepared venom. The possibilities of securing protection by means of the serum of immunised animals have lately engaged the attention and been the subject of experimental observations in France by Calmette, and in Edinburgh by Professor Fraser.

"Audi alteram partem."

"THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK."

To the Editors of THE LANCET.

SIRS,—This subject, as Dr. Shettle says in the last issue of THE LANCET, is of deep interest and of great importance. I believe if we could understand it rightly it would give us the solution to many physiological problems. With your permission I would attempt to give a simpler explanation of the phenomena observed. That strong arterial contraction, and engorgement of the large veins and right side of the heart are present in death from electric shock cannot, I believe, be contested. The contraction of the arteries is unquestionably due to a physical cause, but I do not think with Dr. Shettle that this cause acts primarily on the contents of the vessels (blood being a conductor), but rather upon the badly conducting or insulating nerves and arterial centres. Faraday taught us long ago that the seat of the phenomena was not in the conductors, but in the insulating medium surrounding them. The electrical energy does not travel by the wire but by the insulating sheath or dielectric surrounding it; the function of the wire is to dissipate the energy crowding into it from the dielectric, which else would take up a state of strain and cease to transmit any more. The blood, fluids, and opaque tissues of the human body act as the conductors, or wires, and the transparent tissues as the dielectrics, and these transmit all the energy. This I have tried to explain elsewhere.[1] The kinetic electricity in traversing such tissues becomes static, resulting in a strain of the medium; the shearing stress of the current has altered the condition of the molecules; there is no displacement of the molecules as a whole, as has been pointed out by Professor Lodge,[2] but of their constituent atoms, and the stress, if strong enough, may result in electrolytic disruption. There is tension along the lines on which electricity is travelling and pressure at right angles to this. This is just the force that would narrow the calibre of the artery; this atomic displacement is most probably propagated along the nerve in the same manner as in the causation of muscular contraction. It is a spring-back force, and under normal conditions would stimulate at make and break of the current, but under the conditions we are considering the molecular structure has been so altered by death that there is no spring-back possible, the arteries remaining permanently contracted.

I am, Sirs, yours faithfully,

Cromer, Sept. 17th, 1895. HENRY MCCLURE.

[1] Transactions of the American Electro-Therapeutic Association, 1893.
[2] Modern Views of Electricity.

MALIGNANT JAUNDICE IN CHILDREN.

To the Editors of THE LANCET.

SIRS,—My attention has just been called to an article by Dr. F. J. Smith on Cirrhosis of the Liver in THE LANCET of Aug. 31st, the text of which is the questioning of a case diagnosed by me as "malignant jaundice" and published in THE LANCET of Jan. 5th this year. Dr. Smith is of opinion that my case was one of "hypertrophic cirrhosis," a disease which he says is "exceedingly rare, usually occurring in quite young subjects and presenting typically a large liver and intense jaundice, with nervous symptoms prominent—in fact, just the picture Dr. Donkin draws of his case." Dr. Smith gives as his reasons for being prepared to admit the existence of such a disease as hypertrophic cirrhosis, first, the authority of Charcot and others, and, secondly, a post-mortem examination of the liver and spleen of a case reported to him from a distance. It may be fairly assumed, I think, that Dr. Smith has no further reasons either for his belief in hypertrophic cirrhosis or for his disbelief in the original diagnosis of my case. The existence of hypertrophic cirrhosis of the liver, with the changes usually described by pathologists, and marked clinically by enlarged liver and jaundice, with nervous symptoms prominent, need not be argued here. But, whatever its nature and definition may be, it is not an acute disease; it occurs mainly in adults and cannot be diagnosed during life except by a demonstration of enlargement of the liver. My case *was acute*, occurring in a child two years old; death took place in a little over three weeks from the onset of any illness and two weeks after the jaundice set in. The liver was *not enlarged* at all as far as clinical examination showed, for it was felt but one finger's breadth below the costal margin, as livers of healthy children two years old may be felt as often as not, and the upper limit of liver dulness was noted as "perhaps a little lowered." I do not desire to contend for the correctness of my diagnosis, for it was but based (a necropsy being disallowed) on analogical inference from two quite similar cases observed clinically by myself and examined post mortem by my colleague Dr. Hebb, who quite concurred in my view that these cases were examples of "malignant jaundice" or "acute yellow atrophy." I have reported them in some little detail in my book on "Diseases of Childhood." But I think I may contend that a careful study of my case, as reported in THE LANCET of Jan. 5th, in no way suggests the diagnosis of "hypertrophic cirrhosis," either as commented on by Dr. Smith or as usually described in the text-books.

I am, Sirs, yours faithfully,

London, Sept. 17th, 1895. H. B. DONKIN.

"THE VOLUNTEER MEDICAL SERVICE."

To the Editors of THE LANCET.

SIRS,—I am obliged to Surgeon-Captain Sleman for his correction of my description of the new badge to be worn by regimental stretcher bearers while efficient, and which I have been instrumental in obtaining for the Volunteer force. The official answer to my application to the War Office on the subject reached me as I was on the eve of starting for the Continent, and having read it hurriedly I trusted to my memory when I addressed my letter to you from the South of France. The ground of the badge is to be white, containing the monogram "S.B." in blue and red enclosed within a red circle one inch and a half in diameter, which "will be worked in wool on cloth of the same material as the tunic." Hence my mistake. The original order for Volunteers to wear the armlet on the left forearm is not revoked, and I presume it will be employed when the bearers act as the stretcher section to their battalion, this new badge being simply a recognition of proficiency to be used in the ranks and identifying such men as are available for ambulance work when required.

I am, Sirs, yours obediently,

W. BAINES, V.D., M.D.,
Surgeon-Lieutenant-Colonel, 1st Middlesex Vol., R.E.

Headquarters, College-street, Fulham-road, S.W.,
Sept. 16th, 1895.

"DEATH FROM VEGETABLE POISONING."

To the Editors of THE LANCET.

SIRS,—The paragraph under the above heading from your Manchester correspondent in THE LANCET of Sept. 14th is,

Digitized by Google

to quote from one of the sentences, "not quite satisfactory." There was no reporter present at the inquest, hence the meagre report in the *Manchester Courier*, whence your correspondent acknowledges he obtained his information. The symptoms were very fully described. There is no difficulty in examining the locality, and I shall be happy to show your correspondent round, when I have no doubt he will be satisfied as to there being a poisonous flora. There are two open spaces, both called Gorton Park, one of which is kept like any ordinary park, and is situated in Manchester, while the park into which deceased went consists of very rough land, partly waste, and is situated in Gorton. I had full notes of the case, which I destroyed only a day or two before your correspondent's paragraph appeared, and which I would have been happy to place at his disposal: but as his taking notice of the affair is rather belated I am deprived of the pleasure of satisfying his curiosity as to the symptoms, and can now only refer him to Taylor's Jurisprudence, where the description of henbane poisoning corresponds to what I observed in this case.

I am, Sirs, your obedient servant,

Gorton, Sept. 17th, 1895. B. W. MACARTHUR.

"OVER-OPERATING IN GYNÆCOLOGY."

To the Editors of THE LANCET.

SIRS,—I have perused the correspondence on this subject with interest, great, but strongly mingled with regret that what has been said so often on the other side should have had so short a remembrance and should have made so little impression. As regards all novelties there are two notable tendencies in the human mind, the first being to run into too great extremes, and the other to resist all things that are new and to be obstinately satisfied with things as they are. Happy are those who can safely steer a middle course. I am curious to know why gynæcology should be picked out now as the special field for opprobrium. No reason has been given, and none can be shown, save that it is the newest field of progress. But it is not far to go back to the introduction of such simple proceedings as tenotomy, concerning which I am sure all of us over fifty can remember how the streets and the lanes were scoured for the squinting and the club-footed; how they were impelled to come in, and how many a decent eyesight which could have been improved by a proper set of lenses was irretrievably ruined by division of the internal recti tendons; how many a useful talipal foot was effectually lamed by unwise division of ligaments and tendons. The physician stands aghast at the apparent ease and certainty with which an operation is recommended and performed in cases which used to haunt his consulting-room for months and years, and the operating surgeon listens with ill-concealed impatience to the pleadings of the physician for a little more waiting, and another try at this, that, or the other form of expectant treatment; whilst there is a third party to the argument who boldly set forth their theories and practice, that whilst pus in the breast should speedily be evacuated, so long as it remains in the pelvis all is well. Of the last the less said the better; it is but a matter of time for their entire disappearance from the discussion. The question lies between the two former, and the pity of it is that both are covertly influenced by another failing of humanity, the difficulty of seeing the whole of a question, and possibly by the still lower motive and belief of the financial taint, each for himself and against the other. This has never been openly stated in the present issue save by Sir William Priestley himself. It was at a meeting of the Obstetrical Section of the International Congress in 1881, in the discussion of a paper which I read on Removal of the Uterine Appendages, in which Sir William said that he feared that in such operations there might be a tendency to recommend them under the influence of a prospective fee at the conclusion of the case. As an answer I told a story, the details of which were quite as well known to Sir William as to myself—a story which showed that the facts and conclusions run exactly the other way. We had under our joint care a lady who had a bleeding myoma and immense wealth. I had recommended removal of the appendages—a course not approved of by Sir William and not favoured by the patient and her friends, and therefore not pressed by me. The result was she remained under my care (occasionally, when death from hæmorrhage was imminent, joined by Sir William), and in bed most of the time, for about thirteen years, when the climacteric relieved her from her severe symptoms at the age of sixty-three or four. During that time her illness cost thousands of pounds, a proportionate share of which fell to the lot of Sir William Priestley and myself. If I had operated on her—with a bagatelle risk of 1·6 per cent. mortality—I should have had probably 150 guineas and Sir William about as much more at the end of a successful case (and I do not think that a fatality would have altered the amount), or somewhere about a fifth of what we actually did get.

If the financial motive is to govern us then I shall go in for tinkering with everybody, for prompt and speedy cures do not pay half as well, and the incident of every operation death involves a heavy financial loss. Let us suppose that the utmost of the charge made against operating gynæcologists is true, and that occasional errors, diminished rapidly by increased experience, have occurred by the performance of operations proved or believed afterwards to be unnecessary—are these more than the inevitable blunders inherent to everything that is human, especially in such a branch of life as surgery, which is in itself so hateful that nothing but wild enthusiasm would ever enable a man to follow it? Let the excess of zeal be corrected, but let it be by instruction in wisdom and righteousness, and not by abuse and ill-treatment. Let the correction be made by those who do not live in glass houses, and who may, therefore, have some likelihood of being able to throw stones without risk of retaliation. Such are certainly not the physicians whose utterances we hear of in anonymous articles, nor are they the authors of behind-the-back slanders. The operating surgeons can certainly lay against such the charge of acts of omission and neglect of canons clearly established, which acts tend to the most frightful disasters. Less than a month ago I waited daily for a summons to a distance to remove a suppurating ovarian tumour. The operation was postponed day after day by a physician who ruled that the patient was not fit for an operation so long as she had a pulse of 130 and a temperature of 104°F., and that we must wait till she improved in health. In vain I pleaded that a return of health was impossible so long as she had pints of pus in her abdomen, and, therefore, I was not surprised, but was exceedingly angry, to receive a telegram from the medical attendant, "—— died this morning." How long is this sort of thing to go on? How long is my reiterated question to remain unanswered, "Why is there to be one canon of surgery for the knee-joint and another for the pelvis?" My colleague, the physician in this case, would promptly have called in someone to evacuate pus if it had been found in the buttock, why should the mere presence of the os innominatum have induced him to prevent me doing the same thing when I found pus on the other side of it?

I could narrate a very long list of cases of this type—so long and ghastly a list that I am convinced that if every shred of gossip that has been uttered against every abdominal surgeon in England, and in order to swell that list thoroughly I will include myself, were true and thoroughly established, it would not weigh a stone against a hundredweight for the mischief done to surgery, to our patients, and to us by the persistent "Wait, wait, wait" of the tinkerers.

I am, Sirs, yours faithfully,

The Crescent, Birmingham, Sept. 14th, 1895. LAWSON TAIT.

"BERI-BERI."

To the Editors of THE LANCET.

SIRS,—I have more than once drawn attention to the fact that though the above disease is very seldom seen in England yet it must be evident to all that year by year we hear of more cases. Various are the signs and symptoms and still more various are the treatments. Having seen some hundreds of cases in Upper Assam, to which place it had come by importation, a few words may be of use to junior medical officers either in Assam or on board ship. The first point noticed with those stricken with beri-beri was their "anæmic appearance," which did not yield to a treatment of iron or arsenic; the patient gradually became worse, fever, dropsy, and dysentery came on, ending in death. A post-mortem having been obtained after great difficulty, hundreds of worms were found in the intestines, but for the most part in the duodenum, these small thread-like worms being found in balls, one ball containing over 250.

Digitized by Google

The best treatment I found to be the exhibition of large doses of thymol, ninety grains or more—given in three doses of twenty grains, thirty grains, and forty grains respectively—in twelve hours, followed by ol. ricini if required. The natives called this the "puggla" or "mad medicine," on account of the sensations. All the motions were collected on muslin and washed, when hundreds of these little worms were to be seen. A few weeks on tonics and good food put the poor patient all right again. Ship medical officers on their voyage home from India and other hot climates should look well into any cases of anæmia amongst the native crew, as all who have any experience of coolies and their black brothers know how easy it is for drinking water to be infected by anyone suffering from this disease. I have some of these worms, and anyone wishing to see them can do so on writing to me.—I am, Sirs, yours truly,

A. WILBERFORCE SHEPERD,
September, 1895. Medical Officer of Health, Cowbridge.

A WARNING.

To the Editors of THE LANCET.

SIRS,—May I state through your columns that it has come to my knowledge that a certain individual unknown to me has been sending begging letters signed with my name to various medical men stating that I have been suffering from nephritis and albuminuria and am in straitened circumstances, and asking that money should be sent to me at Great Ilford, Essex? The whole story is a fabrication, and I hope none of your readers have been taken in by it.

I am, Sirs, yours truly,
Micklegate, York, Sept. 17th, 1895. D. S. LONG, M.D.

"SPECIALISM IN MEDICINE."

To the Editors of THE LANCET.

SIRS,—Specialists as a class aspire to a position of leadership in medicine, or, at all events, in certain branches of it. Nevertheless, "A Specialist," in THE LANCET of Sept. 14th, appears to justify acts of dishonesty on the part of his *confrères*, which he makes no attempt to deny, by bringing a countercharge of exaggeration against the rank and file of the profession. Nor does the case he cites necessarily support his charge. For, even assuming that he was right and the case was one of "simple sore throat," and not "diphtheritic," it does not follow that the "neighbouring practitioner" was not acting *bonâ fide* when he pronounced it the latter. Allowing, however, that "A Specialist's" construction of the incident was correct, it must be remembered that among so large a body of men as general practitioners black sheep are sure to be found. As to homœopathists, whose ways he quotes, these no more concern the present issue than do those of quacks.

I am, Sirs, yours faithfully,
Sept. 17th, 1895. A GENERAL PRACTITIONER.

TYPHOID AND CONTINUED FEVERS AMONGST OUR SOLDIERS AND SAILORS IN THE MEDITERRANEAN.

(FROM AN OCCASIONAL CORRESPONDENT.)

THE following facts, which are believed to be as correct as they can be obtained otherwise than from official sources, are certainly suggestive both as regards the nature and the amount of illness which has recently been prevalent in the Mediterranean, and as to the manner in which the convalescents therefrom are sent home.

The Peninsular and Oriental steamship *Valetta* arrived at Plymouth on the night of Sept. 10th last, having on board a complement of some 300 persons, including the crew and numerous first- and second-class passengers. The *Valetta* was on a voyage from Bombay to London and after discharging some passengers at Brindisi had called at Malta on Sept. 3rd. She there took on board a number of so-called convalescents from the naval and military hospitals. These were brought to the ship in a large barge covered with an awning, and the majority of them were so ill that they had to be carried on board in cots. This work was done by a party of sailors detailed for the purpose from a man-of-war in the harbour. Amongst the invalids were four naval officers (all of whom were so ill as to require to be carried on board in cots), and the remainder were sailors and soldiers of various grades, seventeen in all. The four officers were accommodated in the first-class saloon cabins and the other invalids amongst the second-class passengers, of which the ship carried 120, nearly every berth being full. Almost without exception the invalids put on board had been suffering from fever, either typhoid fever or that form of continued fever known as Mediterranean fever. Of the officers three were admittedly recovering from true typhoid fever, as was probably also the case with the fourth.

The stimulating effect of the prospect of going home and sea air had speedily a beneficial effect on most of them. One officer improved rapidly and another was soon able to be on deck, though evidently very weak; but one was not able to leave his berth at all during the voyage, and another, though he managed to get up and walk with assistance on to the tender at Plymouth on Sept. 10th, had only been able to get on deck a few times previously. The invalided sailors also markedly improved in health. Cots were sent on the tender to meet the invalids landing at Plymouth, but were only used in the case of one officer. In this case the patient was in an acute stage of illness on the day of landing, with high temperature, &c. (104° F. the previous day), and other symptoms of severe relapse. The other invalided sailors, although looking very ill, had improved considerably on the voyage. The invalided soldiers went on to London. They did not appear to have improved so much. Those able to get on deck presented a miserable appearance, and four of them had been unable to leave their berths during the greater part of the voyage.

After discharging the invalided sailors and some passengers at Plymouth the *Valetta* proceeded to London and reached the Albert Docks on the morning of Sept. 12th. Even at that date two of the soldiers were very ill; one had only been able to get on deck on the previous day, and another had not been able to leave his berth at all since he was put on board at Malta. These soldiers did not know whether they were bound for Netley or where, though probably someone eventually met them on landing. As regards medical attendance and diet, the invalids were most carefully and ably looked after by the surgeon of the ship. The provision made for nursing in the case of the soldiers was *nil*, and the four who for a long time were unable to leave their bunks or wash themselves had to depend upon the good offices of their fellow sufferers or of the passenger stewards. The sailors (officers and men) were somewhat better off, as amongst the sailors invalided with fever was a naval sick bay steward from the *Itamillies*, who was really convalescent and who was of great service to those requiring nursing assistance and in directing the stewards upon whom the carrying out of various sick-room details necessarily fell, especially in the case of the invalid officers.

The above facts suggest two chief points for consideration. How far, having regard to the travelling public, is it justifiable for such cases to be transmitted in an ordinary passenger vessel, and how far is it proper for the sake of the patients themselves that they should be sent a voyage under such conditions? Although that form of continued fever from which the majority of the cases referred to above had suffered, and known variously as Mediterranean fever, Malta fever, typho-malarial fever, &c., has admittedly a very close resemblance to typhoid fever, and by some medical officers of experience is considered as identical with that disease, though modified by local climatic conditions, it is not usually considered communicable; there were, however, amongst the invalids carried on board at Malta undoubtedly several cases of true typhoid fever, and the natural history of this disease certainly indicates that it is most undesirable that those performing any office of nursing in such cases should have anything to do with food distribution except under very strict conditions of disinfection and precision in cleanliness. The use of the terms "convalescents" and "non-infectious fevers" gave a large amount of very salutary confidence to the other passengers in the vessel, but no precautions were taken to isolate any of the latrines, and the ship stewards, who were said to do various nursing

Digitized by Google

offices for the patients, handed food to the passengers at meal-times as usual, and although the ventilation of the Peninsular and Oriental steamships is most free and efficient the conditions of life on board a ship are necessarily more intimate than they would be on shore. Probably the risk of infection to other passengers was exceedingly remote, but what could not be carried out in the case of cholera without great risk should not be attempted in the case of typhoid fever and allied diseases. As regards the patients themselves, there can be no question that cases of acute disease, although approaching convalescence, should not be sent a voyage except under suitable and special conditions of accommodation and nursing, and then only when sufficiently recovered to bear the journey well. The admitted benefits, in cases of prolonged and tardy convalescence from continued fever, to be derived from a sea voyage and a homeward journey can then be most fully taken advantage of. The stimulating effect of the latter may be judged from the statement made on good authority that when it became known in Malta Hospital that a draft of invalids was about to be sent home the average temperature of the convalescent cases fell markedly.

As regards the health of the fleet generally, the hot weather of early autumn is the season when attacks of Mediterranean fever are to be looked for; but, unless current local reports have much exaggerated matters, there was an exceptional outbreak of true typhoid fever on several vessels of the fleet during its recent cruise in the Levant. Popular opinion in the fleet associates this outbreak with the prolonged stay in Boudrun Bay in the neighbourhood of Smyrna, where the fleet lay for some weeks and during the whole of July. Some ships suffered much more than others, and the *Collingwood* is said to have had upwards of 50 men attacked, of whom 7 died. When the *Valetta* left Malta there were 175 patients in the naval hospital, and every time the store ship returned from the fleet she was said to bring additional invalids. If these statements as to an extensive outbreak of undoubted typhoid fever be correct, doubtless some explanation and report will be forthcoming in due time.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

THE SITUATION AT PORTSMOUTH.

THE question of medical aid for benefit clubs, always delicate and complicated, is fraught with an extra and local difficulty at Portsmouth. As a general abstract statement it may be said that when benefit societies were first organised and medical men lent willing aid to the work it was never foreseen that these societies would grow so rapidly and become the gigantic and powerful institutions that exist to-day. Then in very many cases the medical officer of such societies thought that if he attended the bread-winner on cheap club terms he would have the other members of the family as ordinary paying patients. Now, on the contrary, the benefit societies want the wives, the daughters, and even the infants to share in the benefits. Thus the hope of creating a general practice by doing club contract work would be reduced to a minimum, if not obliterated altogether. At Portsmouth the Manchester Unity, which is the largest branch of the Oddfellows' Society, now desires to admit children of both sexes from the age of three months. Actually, only male children who are three years old are admitted to medical insurance. They pay from 2*s.* to 2*s.* 6*d.* per annum according to the lodge. The men pay 4*s.* and it is proposed to form lodges for adult females at the same rate of payment. The Foresters and the Druids pay 4*s.* for males and 2*s.* for every child from three to eighteen years of age. The Manchester Unity wishes to admit children of both sexes from three months. One lodge proposes 2*s.* 6*d.* for infants from three months to three years, 2*s.* for boys from three years to eighteen years, 2*s.* for girls from three years to fifteen years, and 3*s.* 6*d.* for girls from fifteen to twenty-one years. After these ages the members would join the lodges for adults. The feeling in the medical profession is naturally very strong against the admission of women and children, particularly as the sum paid for the adult males is so small. The Manchester Unity has some 5000 members at Portsmouth, the Foresters 4000, and the Druids 1200. Then there is the Temperance Society of the Rechabites. The latter pay 3*s.* 6*d.* for adults and 2*s.* for children; and quite recently, without so much as consulting their medical officers, they decided to admit infants from the age of six weeks. Many of these Rechabites are shipwrights and dockyard artisans who are in receipt of good wages, live in comfortable houses, and formerly easily payed proper fees for the medical attendance given to their children. Now these same children are brought to the Society's medical officers, who have to attend to them for the meagre sum of 2*s.* a year.

Unfortunately, in resisting these encroachments the medical profession at Portsmouth are met by the special local difficulty to which I have alluded. The benefit clubs reply to all such objections by pointing to the Dockyard Medical Benefit Society, which takes in all the members of the families concerned, and argue that they must do the same. This Dockyard Society was started at Deptford some twenty-five or thirty years ago. Then when much of the shipbuilding work for the British Navy was transferred to Portsmouth the society was implanted in the Portsmouth Dockyard. None are admitted except persons who work in the dockyard, and the members pay ½*d.* per week for themselves and for each member of their families. The society is managed by the workers themselves and the whole of this sum is given to the three medical men engaged by this organisation. The society is well organised; the money is collected free of expense. There used to be a guinea fee allowed for accouchements; but some six years ago the society resolved to reduce this to 15*s.* and 7*s.* 6*d.* for miscarriages. All the three medical officers were also expected to meet in consultation without receiving any extra fee. No limit was put to age, and one medical officer told me pathetically that he had been asked to give club papers for the enrolment of a child three days old. Two of the medical men, Dr. Blackman and Mr. Goss, refused these increased burdens and resigned; but their places were quickly filled by other medical men, who eagerly accepted these posts. Some of the dockmen, however, sympathised with the medical officers who had resigned and formed another society, where the terms are more favourable to the profession.

The great question for the moment is how to prevent all the benefit clubs of Portsmouth from following the example of the Dockyard Society. Some of the medical men concerned have shown me their ledgers. These prove that men who only pay 4*s.* a year for medical attendance as members of clubs pay 2*s.* 6*d.* a visit to their club officer when he attends members of their family. One account showed that these visits amounted to £7 10*s.* in the course of the year. In other cases £2, £3, £5, and £6 were paid by members of clubs for attendance on their families. These sums are paid without complaint, and this makes it worth while to be a club officer. But all these advantages will be abolished if the families of members are also to be taken in by the clubs. A struggle is likely to ensue on this point, and the question arises, first, whether the medical profession at Portsmouth is sufficiently well organised to hold its own against the clubs, and, secondly, whether they will be loyally supported by the members of the profession outside Portsmouth. As already described at the last annual meeting of the British Medical Association, a Medical Union has been constituted at Portsmouth. Its president is Mr. F. Lord, who has a very extensive club practice in the town; the vice-presidents are Mr. James Green and Dr. Lysander Maybury. Dr. T. Frederick Pearse, 12, Norfolk-street, Southsea, is the honorary secretary; and Dr. J. G. Blackman, Poplar House, Kingston-crescent, Portsmouth, is the honorary treasurer. This union was formed to defend the interests of the medical profession, to encourage friendly relations between members of the profession, to enable them to obtain advice and united support, to facilitate interchange of views, and to secure combined action and consolidated influence when difficulties arise. Such is the general object of the union, but its particular purpose is, first, to "consider and take action upon the relations of medical officers with friendly societies and medical aid associations, and with regard to Poor-law and other official appointments; secondly, to establish, maintain, and circulate among members of the union a patients' black list; thirdly, to promote the improvement of medical fees"

These ends are to be attained, with regard to friendly societies, by the united action of the members of the Medical Union, so as to enforce a wage limit beyond which members

Digitized by Google

of friendly societies shall not be admitted to participate in medical benefits. It must be admitted that, under this heading, little or nothing has been done. Everyone acknowledges the necessity of a wage limit. Even the members of the friendly societies themselves do not deny the justice of this demand. But who is to define the wage limit, and on what principle is it to be established? Shall there be a difference between married and unmarried men? Undoubtedly a bachelor earning £1 a week is much better off than a married man with a family who earns 30s. a week. Then there is the more complicated question of constant employment. Here, at Portsmouth, men work in the Royal Dockyard for a smaller wage than they would earn in the same trade if working outside, but they have constant employment and pensions for old age. There is no risk of loss of employment through the fluctuations of trade, through fire, or the employer's bankruptcy; thus, taking an average of a life, the man who is paid 35s. in the dockyard earns more than the man whose wages outside the dockyard and for the same sort of work usually amount to £2 per week. How is the wage limit to be established in that case and who is to estimate the relative income of the two men? Supposing, however, answers can be found for these and many other similar questions as far as Portsmouth is concerned, is the Medical Union to establish a wage limit for Portsmouth alone without taking into consideration the state of affairs in other parts of the country? Already at Cork it has been proposed to fix the wage limit at £4 per week, but every medical man I have spoken to on the subject repudiates such a proposal and considers this wage limit far too high. As no town can fight its battle alone, but its action must be approved and supported by the medical profession throughout the country, a general consensus of opinion on this question of wage limit must be obtained.

The Portsmouth Union also proposes to enforce the medical examination of the new members of friendly societies and the payment of a special fee for such examination. Members of clubs who do not subscribe to the surgeons' fund and who require certificates are to be made to pay for such certificates. For instance, I had the case of a man who belonged to the Foresters' Society explained to me. He paid for the medical benefits as a Forester, but he wanted to join the Druids for financial benefits only. Before the Druids would thus insure him they wanted a medical certificate, and sent him to their medical officer, who was also the officer of the Foresters' Society. The latter obtained no fee for examining the man, and as he did not pay for medical benefits from the Druids the officer got no advantage whatsoever for examining this case and giving a certificate. The wife of this man was also sent to the officer to be examined before she was admitted to funeral benefits. Again the officer received no fee. Indeed, men constantly come for examination, they pay no fee, and there is no evidence to show that they are going to pay for medical insurance. If they are examined merely for financial benefits then the medical officer's work is absolutely unrequited. The Medical Union further urges that visiting members should not be allowed medical benefits except after a satisfactory medical examination. The Southsea district of Portsmouth is a health resort. Many old members of benefit societies, who have paid their subscriptions for many years in the business centres where they have lived and worked, retire in their old age and establish themselves at Southsea at that period of declining life and health when they are likely to require the most medical assistance. Because they belong to the same societies that exist at Portsmouth these so-called visiting members expect to be attended by the Portsmouth medical officer of their society. This throws an altogether unfair burden on such medical officers at health resorts or places where people go precisely because they are delicate, old, or ill.

The other objects of the Portsmouth Medical Union are to alter the tenure of office so that there should be a three months' notice on either side, to raise the rate of subscription for juveniles, and to obtain the united action of members of the union with regard to the admission of females to the medical benefits of friendly societies, but I have already dealt at length with these points.

The rules of the Portsmouth Medical Union are that every registered medical practitioner shall be eligible for membership on payment of an annual subscription of 5s. to cover working expenses. Besides the officials whose names are given above there is a committee of six members, and four form a quorum at committee meetings. Officers and committeemen are elected at each annual meeting, and the committee has power in the interval to fill up such vacancies as may occur. The committee is to meet once a month or oftener if necessary. On a requisition of six members a general meeting of the whole union must be called, but such meeting shall discuss no other question than that for which it was convoked. The most important rule is that which exacts a personal pledge from all members of the union that they will not oppose any practitioner "in any course of action which he may take with the concurrence of the committee in his official capacity concerning any public appointment." This does not implicitly pledge the members to improve their positions; but, as it includes cases where medical men resign their posts on a matter of principle, it will, if carried out, tend to greatly improve the conditions under which club work is done. There are some two hundred medical men at Portsmouth, but the majority are retired from the army or naval service. There are about eighty medical men in practice at Portsmouth, and they have all signed this pledge. All are therefore in honour bound not to accept any post which may be vacant because its former occupant has, with the approval of the committee of the Medical Union, resigned on a matter of principle. If, however, any member proves false to this pledge then "any member acting, in the opinion of a special meeting called for the purpose, contrary to the laws and regulations of the union shall, upon a majority of at least three-fourths of the members present, be suspended or expelled, and without appeal, from the advantages of the union." A fourteen days' notice must be given for the convocation of such a meeting. The great question remains whether such expulsion from the union will in itself be in all cases a sufficient deterrent to ensure implicit obedience on the part of all the members of the Medical Union. If so, then will not some medical men from other towns, who do not belong to the Portsmouth Union and who have not given any pledge, come and take the vacant posts? What in that case will be the action of the Portsmouth Medical Union? These questions show how necessary it is that medical unions should be national as well as local.

Portsmouth, Sept. 10th.

(To be continued.)

THE FIFTH INTERNATIONAL CONGRESS OF OTOLOGY.

(FROM A SPECIAL CORRESPONDENT.)

THE organising committee, of which Professor Vittorio Grazzi is president, is in daily receipt of fresh "adhesions" to the membership of the Congress, and of those already sent in I may mention the following: Dr. Abery (Copenhagen), Dr. B. Alvarez (Madrid), Dr. Arsian (Padua), Dr. Ascensio (Spezia), Professor Avoledo (Milan), Mr. Baber (Brighton), Dr. Baratoux (Paris), Dr. Barkan (San Francisco), Dr. Barr (Glasgow), Dr. Bèco (Liége), Dr. Bobone (San Remo), Dr. Botey (Barcelona), Dr. Boucheron (Paris), Dr. Brieger (Breslau), Dr. Bronner (Bradford), Dr. Brunetti (Venice), Dr. Burnett (Philadelphia), Dr. Buscaroli (Imola), Dr. Capart (Brussels), Dr. Carralero (Madrid), Dr. Chincini (Rome), Dr. Coosemans (Brussels), Dr. Corradi (Verona), Professor Cozzolino (Naples), Dr. D'Aguanno (Palermo), Sir William Dalby (London), Dr. Daly (Pittsburg), Dr. Delie (Yprès), Dr. Delsaux (Brussels), Dr. Delstanche (Brussels), Dr. de Rossi (Rome), Dr. Dundas-Grant (London), Professor Ferreri (Rome), Professor Ficani (Palermo), Dr. Flatau (Berlin), Dr. Galetti (Milan), Dr. Garzia (Naples), Dr. Gellè (Paris), Dr. Goris (Brussels), Professor Gradenigo (Turin), Professor Grazzi (Florence), Dr. Grünwald (Munich), Dr. Hartmann (Berlin), Dr. Haug (Munich), Dr. Heimann (Warsaw), Professor Lannois (Brussels), Dr. E. Law (London), Dr. Lichtwitz (Bordeaux), Dr. Locatello (Pesaro), Dr. Lubet-Barbon (Paris), Professor Lucä (Berlin), Dr. Macnaughton-Jones (London), Dr. Martin (Paris), Professor Masini (Genoa), Dr. Menière (Paris), Dr. Mongardi (Bologna), Dr. Morpurgo (Trieste), Dr. Moure (Bordeaux), Dr. Okuneff (St. Petersburg), Professor Ottolenghi (Siena), Dr. Palazzolo (Catania), Professor Politzer (Vienna), Dr. Pritchard (London), Dr. Rattel (Paris), Dr. de Roaldes (New Orleans), Dr. Royat (Lyons), Dr. Rutten (Namur), Dr. St. Clair Thomson (London),

Digitized by Google

Dr. Schiffers (Liége), Dr. Secchi (Bologna), Dr. Secretan (Lausanne), Dr. Sexton (New York), Dr. Soffiantini (Novara), Mr. G. Stoker (London), Dr. Strazza (Genoa), Dr. Suarez-de-Mendoza (Antwerp), Dr. Sune y Molist (Barcelona), Dr. Szenes (Budapest), Dr. Verdos (Barcelona), and Professor Zufai (Prague).

The programme has been finally arranged and will begin on Sunday evening, the 22nd inst., at 9 o'clock, with a *réunion* in the house of the President, Professor Vittorio Grazzi.

On Monday, the 23rd inst., at 10 A.M., the Congress will be inaugurated in the Great Hall of the Istituto di Studi Superiori, followed by a sitting from 2 P.M. to 4 P.M., and in the evening there will be a concert given in honour of the Congressisti at the Circolo degli Artisti. On Tuesday (24th inst.), at 8.30 A.M., and at 2 P.M. there will be two sittings; at 9 P.M., a banquet at which the foreign Congressisti will be entertained by the President, Professor V. Grazzi. On Wednesday (25th inst.), again, at 8.30 A.M. and 2 P.M., there will be two sittings, and at 4.30 P.M. a reception at the Palazzo Comunale in the Quartiere Leone X. On Thursday (26th inst.), at 8.30 A.M., there will be a sitting, followed at 1.30 P.M. by another, at which the Congress will be formally closed. At 4 P.M., by special invitation of the Communal Administration, there will be an excursion, conveyed by special electric tram, to Fiesole; and at 7.30 a public banquet will be given to the foreign members of the Congress by their Italian colleagues and the citizens of Florence.

Concurrently with the Otological Congress there will also be held in Florence a meeting of the Italian Association of Laryngology, Otology, and Rhinology.

Florence, Sept. 14th.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Rowdyism Rampant.

MANY complaints have lately been made from the suburbs of the city as to the bad behaviour of roughs and the wilful damage and destruction of property. Nor is the viciousness confined to the outlying districts. The city magistrates had a long day on the 16th inst. investigating charges of assaults upon policemen by various gangs. The favourite instrument of aggression is the buckled belt. Wielded with the facility of familiar use this becomes a formidable weapon, capable of fracturing skulls and doing grievous injury to the inoffensive and unarmed. Policemen are cautioned to use their truncheons with discretion, but in the midst of a conflict, often savage and unprovoked, human nature must necessarily assert itself in the interest of self-protection. The law should be strong in protecting the men who are employed to uphold its power. Light sentences produce but little deterrent effect, and fines are readily paid by the companions of the guilty. A recognition of the *argumentum ad hominem* should be more effectual in suppressing these cowardly attacks, the results of which give our hospitals much work and divert the sources of charity from the more deserving.

Cycling Dangers.

The more general use of cycles brings with it certain dangers. Two instances of death from cycling accidents have lately occurred in this district, each from causes apparently accidental. In one the rider was thrown off his machine, falling under the wheels of a passing cab; and in the other the foremost rider of a tandem sustained a fracture of the skull which proved fatal. Care is evidently necessary as to speed, and attention to the accurate working of the machine. Trifling defects or inexperience place the riders in crowded thoroughfares in much danger, not to omit that incurred by the many pedestrians, whose movements add to the possble risks of both.

Paraffin Lamps.

The old story of paraffin lamp explosions, in its repetition, emphasises the demand that some measures should be framed to make the danger less possible. Accidents of this kind are of almost daily occurrence, and yet could be easily prevented. As long as cheap lamps can be purchased they will be used and the danger will still continue. No amount of reiteration will be successful in the way of warning. The Legislature evinces a fostering care with regard to unhealthy trades and restricts the liberty of the subject in many wise ways. Why should it not pass some law with regard to the protection of person and property in this direction?

Sept. 17th.

LIVERPOOL.

(FROM OUR OWN CORRESPONDENT.)

Proposed Conference of Sanitary Authorities.

THE position of Liverpool as a great maritime highway is now accentuated by the fact that the Manchester Ship Canal can only be reached *vid* the river Mersey. So far as relates to port sanitary matters this has been already alluded to by your Manchester correspondent in last week's issue of THE LANCET. Acting in conformity with the suggestion of the Local Government Board the Liverpool Port Sanitary Committee have instructed the town clerk to make arrangements with the authorities riparian to the Manchester Ship Canal, or abutting upon the waters constituting the port of Manchester, for a meeting in Liverpool. It has also been arranged that the Lord Mayor, the chairman, and the deputy chairman of the Port Sanitary Committee, with Messrs. Paull and Walker, Dr. Clarke, the town clerk, and the medical officer, Dr. Hope, shall be appointed to represent the Liverpool Port Sanitary Authority at the proposed conference. It is expected that an early date will be fixed.

Small-pox, Vaccination, and Isolation.

An addition to the many illustrations already given as to the protective powers of vaccination, and also as to how small-pox is spread, was made at Wigan on the 16th inst. A woman residing at Longshoot Scholes was summoned for failing to notify a case of small-pox to the sanitary authority. It appeared that an outbreak recently took place in defendant's house. There were eight children in it, and the child that died from small-pox was the only one amongst the number that had not been vaccinated. Eleven other cases were traced to the outbreak in defendant's house. The bench imposed the full penalty of 40*s.* and costs.

Sept. 17th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

A Public Health Difficulty at Port Glasgow.

A CURIOUS position has been reached as the result of a dispute between landlord and tenant in regard to the responsibility for a nuisance in connexion with a dwelling-house in the burgh of Port Glasgow. The tenant, who is a medical man, communicated with the Local Government Board, from which instructions were sent to the local authority to proceed against the owner of the property under Section 255 of the Burgh Police Act. The representatives of the landlord then offered to comply with the section of the Act provided the certificate which the Act requires were produced. But it has been found that no medical man in the burgh possesses the public health qualification, which is needed in order to sign the certificate, and so the local authority cannot move further in the matter.

Glasgow: Fatal Accident Inquiries Act.

This new law, under which fatal accidents are reviewed before a sheriff and jury, has now been put in force in a number of cases. Some differences of practice on the part of different sheriffs with regard to the action of the juries have already occurred. Thus, in one recent case, in which a railway shunter was killed whilst engaged in his occupation, the jury proposed to add to the statement of fact in the verdict an expression of opinion that the system of signalling was defective; but the sheriff altogether discouraged this and informed the jury that to do so would be to take upon themselves a responsibility to which they were not called. In other cases, however, the sheriff, whilst telling the jury they were only compelled to consider the immediate cause of death, has received and even encouraged expressions of opinion in reference to the question of personal responsibility for the accident.

Hospital Vacancies.

Professor Coats, M.D. Glasg., has resigned his position as pathologist to the Royal Hospital for Sick Children,

Digitized by Google

Glasgow. He has held this office since the establishment of the hospital in 1882. There are also vacancies on the medical side of the out-patient department, and a qualified clinical assistant is to be appointed to the dispensary. The Western Infirmary is advertising for applications for a vacant position on the medical dispensary staff, and there is a surgical vacancy at the Central Dispensary.

Infectious Diseases in Glasgow.

The city is now practically free from small-pox, only a single case being at present in hospital. Scarlet fever and to a less extent enteric fever are, however, on the increase. The number of cases of the former known to exist on the 14th inst. was 555, whilst 184 patients suffering from enteric fever were noted in the medical officer's report.

Aberdeen Royal Infirmary.

The infirmary directors have now fixed on a site for the new convalescent hospital. It is to be built on about four acres of ground feued from Mr. William Pyper on his property of Hillhead Pitfodels. It will accommodate about twenty-five patients and is within twenty miles' easy walk of Cults Station, commanding a far-reaching view of the Deeside valley and mountains. The old Convalescent Hospital and grounds at Lochhead have been disposed of for a satisfactory price to the Royal Asylum. The Infirmary Board have also resolved to appoint an assistant anæsthetist to act with Dr. Edmond, the present chloroformist. The funds of the hospital fell short of the expenditure last year by some £500, and the chairman announced that he had addressed appeals to various parishes throughout the county whose contributions fell far short of the amount spent on patients sent from them, and that he had received hopeful replies.

Aberdeen University: The Inaugural Celebrations.

As I informed you last week the University Court and Senatus resolved to postpone till December the celebrations held to inaugurate the new buildings at Marischal College as a mark of respect to the memory of the late Mr. Charles Mitchell, LL.D., in whose honour they were largely to be held. Since then his son, Mr. C. W. Mitchell, has informed them that it would be more in accordance with his mother's and his own wish that the celebrations should be held as previously arranged in October. A meeting of the Court, therefore, is to be held this week to consider which course they shall pursue.

The Health of Aberdeen.

The zymotic diseases notified for the week are: scarlet fever, 14; typhoid fever, 8; whooping-cough, 31; erysipelas, 4; puerperal fever, 1; choleraic diarrhœa, 1; total, 59—being 22 cases fewer than in the preceding week.

Sept. 17th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

Irish Tourist Association.

THE Presidents of the Royal College of Physicians and the Royal College of Surgeons of Ireland attended among the deputation introduced to his Excellency the Lord Lieutenant by the Lord Mayor of Dublin on the 7th inst. Many suggestions for the entertainment and accommodation of visitors to Ireland were made by the speakers on the occasion, while a novel proposal emanated from Sir Thornley Stoker, who called attention to the fact that Ireland is traversed almost from side to side by two large canals, and to the advisability of utilising these fine streams for the transit of house-boats.

The Will of the late Sir George Porter.

Probate of the will of the late Sir George Porter, LL.D., F.R.C.S. Irel., &c., who died on June 16th last, has been granted to his widow, Dame Julia Porter, and to his son, Sir William Porter, Bart., power being reserved to grant probate also to Mr. Charles Leeper. The personal estate was valued at £57,366. The testator bequeathed to Lady Porter £250 and the use of his house in Merrion-square, her yearly income to be made up from the trust-fund of her marriage settlement to £1050 for her life. There are, with other bequests, legacies of £500 each to the testator's friends Sir George Owens, M.D. Glasg., and Mr. B. Whitney; and a legacy of £100 to his nephew, Mr. Charles Leeper, in consideration of the executorship.

Fines for the Sale of Unsound Meat in Dublin.

The Dublin corporation has recently brought two summonses against the Jewish Meat and Provision Company of this city for the sale of unsafe meat. For the defence it was pleaded that sudden decomposition may have taken place in the meat after it was sold in consequence of lightning, which prevailed on that evening, and also owing to the unusually hot and moist condition of the atmosphere. It also transpired that the meat was killed by the above company with the greatest care—with greater care, in fact, than was used by butchers of the Christian persuasions. The practice was that the Rabbi or other ecclesiastical persons of importance examined every animal for soundness before it was killed, and ascertained that the process of killing, bleeding, &c. was done in the best possible way. The animal, after it was killed, was opened and the portion of the stomach known as the caul drawn out so that its contents could be examined. Particular portions of the animal were marked for those of the Jewish persuasion by means of a peculiar pencil which writes on fat. Subsequent evidence, including that of Mr. Purcell, L.R.C.S. Irel., proved, however, that the meat sold was in an unsafe condition. A fine of £5 in each case was imposed.

The Recent Report on the Belfast Workhouse.

At the meeting of the Belfast board of guardians held on Sept. 10th a report was presented by a sub-committee recommending that a special room should be allocated for the examination of patients on admission and that an observation ward should be set apart for those supposed to be suffering from lunacy until their condition should be finally determined. The sub-committee approved of a bath and lavatory being provided for the separation wards, and they recommend that a male nurse be appointed as soon as possible for the male lock ward. As to the resident medical staff, the sub-committee ~~are of opinion that~~ these officers should verify and sign the medical weekly return, the book being counter-signed by the visiting medical officers.

Hospital Saturday, Belfast.

The collection for the Belfast Royal Hospital was made on Sept. 14th, but, notwithstanding beautiful weather and every effort on the part of those helping, not more than £300 have been realised. In 1885, the first year of the collection, £500 were subscribed, and each year it grew less, until it reached its lowest water mark in 1892. Last year £400 were contributed. Many people think that until the hospital is put on the city rates it will not be in a permanently sound financial condition.

Queen's College, Belfast.

Rev. W. Nicholas, D.D., and Rev. Douglas Walmsley, B.A., have been appointed Deans of Residence of the College to fill up death vacancies.

Transfer of Lunatics from Asylum to Workhouse.

On Sept. 14th an inquest was held in the Belfast Union Hospital in reference to the death of a young woman who died in the lunatic department on the 12th inst. It would seem that the deceased was admitted to the Belfast Asylum in 1889, having been transferred from the Ballymena Workhouse. She was suffering from dementia, but was quiet in manner and was delicate in health. Owing to the overcrowded state of the asylum she was later transferred to the lunatic department of the Belfast Workhouse, this being done under an old arrangement, as now only patients belonging to the Belfast Union are sent to the workhouse from the asylum. When admitted to the lunatic department of the Belfast Union Hospital she was pregnant and was suffering from disease of the lungs. After being confined she was put in a bed in the lunatic ward, where she had been continuously since last March and where she died from phthisis. In his remarks to the jury the city coroner said that every lunatic should be removed from the workhouses of Ireland and placed in properly equipped asylums. In his opinion, the transfer of a delicate, pregnant woman like the deceased from a properly equipped asylum to a workhouse, which was never intended for the reception of the insane, would undoubtedly have a prejudicial effect upon her health. The jury returned the following verdict: "That the deceased died from consumption; that a Royal Commission to inquire, amongst other things, into the reception and treatment of lunatics in workhouses is imperatively needed; that, in the opinion of the jury, workhouses were unfitted and never intended for the treatment of the insane; and that the coroner be requested to forward a copy of the verdict and the depositions to the Chief Secretary of Ireland."

The Belfast Hospital for Sick Children.

The Belfast Hospital for Sick Children, which has been

Digitized by Google

closed for several months, will be reopened on Sept. 23rd. In the interval the sanitary arrangements have been entirely altered, a new wing, properly isolated, having been built, in which on each floor there are bathrooms and closets. Formerly there was a laundry on the ground floor; it has been decided to remove it to the convalescent home in the country, and the space thus gained has been utilised in an extension of the extern rooms for the greatly increased out-patient work. The surgical theatre has been enlarged and improved in every respect in accordance with the demands of modern science. The hospital is now one of the most perfect in Belfast, and these new changes and improvements will bring it into line with the most modern institutions of the kind in the United Kingdom.

The Battle of the Clubs at Cork.

Mr. O'Neill, secretary to the Amalgamated Clubs, wrote a long letter to the local papers, in which he claimed that the late conference had resulted favourably for the clubs. For the purpose of proving his contention he published what purported to be the minutes of the proceedings. He tabulated the rules of the medical men, and opposite about half of them wrote the word "expunged." Now, taking the very first rule, I find it proposes that members should pay according to their income. With regard to that the club delegates suggested that it would be very difficult to devise a plan for ascertaining the incomes of members of any one club; but if the sliding scale were not insisted on each club would be willing to pay any sum the medical men were likely to ask. The medical delegates considered the proposition worth bringing under the notice of the profession, and Mr. O'Neill, in his minutes of the proceedings marks "expunged" opposite Rule 1. The supposed disappearance of Rule 1 forms part of what is represented as a win for the clubs. In this morning's papers the medical delegates publish the subjoined reply, which tends to demolish the pretensions of the clubs.

Cork, Sept. 16th, 1895.

SIR,—In his letter relative to the recent conference on the subject of medical clubs, Mr. O'Neill states that several of the rules adopted by the doctors were "expunged," but the Mayor can certify that we stated we were there simply to discuss the rules, and that they could be altered only by the general body of the profession. As a matter of fact, not a single rule has been expunged. We contended on behalf of the profession mainly for two points: (1) that the present ridiculously low rate of remuneration should be increased to a just and reasonable amount; and (2) that persons in receipt of over £200 a year should not be allowed to avail themselves of medical services at club rates. The delegates would be willing to agree to our first proposal, and with regard to the second they would be prepared to prevent the admission of new members whose incomes would exceed £200 a year. That looked very like conceding nearly all we asked, though interested parties endeavoured to make the public believe that our just demands were monstrous and unreasonable. No doubt the club delegates were anxious to retain existing members, no matter what their incomes may be, but we do not believe the profession at large would acquiesce in that arrangement, as we have since the conference ascertained that a very large number of club members, whose names are before us, are in receipt of incomes varying from £400 to £600, and even £800 a year.—We are your obedient servants,

NATHANIEL J. HOBART, M.D., | EDWARD MAGNER, M.D.,
EDWARD R. TOWNSEND, M.D., | JOSEPH GUISANI, M.D.,
HENRY CORBY, M.D., | PHILLIP LEE, L.K.Q.C.P.I.,
Medical delegates at the late conference.

P.S.—The absence of our honorary secretary prevented the publication of this letter at an earlier date.

I have every reason to believe the Cork medical men will soon enter on a still more active campaign against the clubs. At an early date they will have under consideration the propriety of forming new clubs to be governed entirely by the medical men themselves. They could then exclude those able to pay ordinary fees; and they would be in a better position to adopt a sliding scale of payment for members. Many members of the Cork clubs are dissatisfied with the present state of affairs, but they do not care to revolt openly and thereby lose the benefits accruing to them in their clubs. Let the Cork medical men offer them similar advantages in a new club and the desertions would be so great that the old clubs would be forced to surrender at discretion.

Sept. 17th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Twenty-fifth Anniversary of "Rome the Capital."

ON Friday, the 20th inst., recurs the twenty-fifth anniversary of the fall of the temporal power, the triumphal entry of the troops of United Italy, and the transference of the capital of the kingdom from Florence to Rome. On the political aspects of the event I have, of course, nothing to say; but in so far as the healing art is concerned, first as to education, then as to practice, and finally as to the results manifested in the public health, the occasion is interesting enough to suggest a few comments. There is no doubt that the conversion of Rome from the capital of the Church into the capital of the "fifth great European Power" has given an impetus to the modern life in the city long immersed in mediæval tradition. The hospitals have become enlarged; their appointments, though still far short of an ideal standard, have been improved; their *personnel* has been increased, and the beginnings at least of a model institution of the kind for the rest of Italy have been made in the Policlinico. Concurrently with this the teaching in the University—theoretical, practical, and clinical—has taken a signal start for the better, thanks to the addition to its staff of such men as the late Professor Moleschott, whose agnosticism and thorough-going adhesion to the evolutionary principle had made him a "persona" far from "grata" to the old *régime*. Further, the necessity of making the new capital as healthy as the influx of population and the residence of royalty and Government demanded, has inspired a more exemplary "nettezza publica" (external tidiness) than prevailed previously, while it has led to the partial reclamation of the outlying Campagna, and the consequent diminution of the "intoxication tellurique" (to use Dr. Léon Colin's happy phrase), which is the proximal cause of malaria. All these are gratifying results of the revolution now being enthusiastically commemorated by "Young Italy"; but there is a reverse side to the picture. Only a quarter of a century divides the old from the new Rome, and there has hardly been time for the modern city to rise to an adequate appreciation and fulfilment of the duties it has assumed. The building operations have been conducted with more haste than prudence, and the interests of the speculator and jerry builder have overborne those of the sanitarian. The water-supply is neither as abundant nor so pure as it was before 1870, with the result that typhoid fever, till then unknown, is now all too familiar to the practising physician. The rapid increase of population has brought with it the "great sins of great cities," and the misery and deterioration of the lower orders is, as usual, manifested most painfully in the very young. Last Christmas his Excellency Dr. Baccelli, on an official visit to the new quarter at San Lorenzo, was shocked to witness the squalor, the indications of premature vice and crime, together with all the saddening prospects the spectacle implies, that met him at every turn. In conjunction with another statesman the ex-minister Finali has set himself at once to devise and carry out measures for the rescue and rehabilitation of the tender youth of the city, and his efforts have been seconded with a zeal and liberality that are of the best augury for his truly philanthropic and patriotic scheme. "We have made Italy, now we have to make Italians" is hardly less true to-day than when Dr. Azeglio uttered the memorable saying a generation ago, insomuch that the commemoration of the crowning act of the nation's unity, now in full progress, could not take a better form than a reinforcement of Dr. Baccelli's humanitarian endeavour and its extended application to all the cities and communes of the kingdom—to all the places, and their name is legion, in which Italy is already paying the penalty of increased responsibilities and hardness of living—a penalty seriously impairing her present and darkening her outlook for the future.

The Croce Rossa Italiana and the Autumn Manœuvres.

By common consent the intervention of the Italian Red Cross at the recent manœuvres was one of the most gratifying features of those exceptionally brilliant evolutions. Invited by the War Minister, the Central Association sent, at its own expense, a fully equipped hospital of 100 beds, which, under the direction of Captain Giacomo Crespi, M.D., the physician-in-chief, took up successive positions at Cittaducale, Madonna della Strada, and Aquila. During the sixteen days of its active service the hospital admitted 130 soldiers, the majority of whom suffered from medical rather than from surgical lesions. Every department of the hospital was brought into play, so that, besides the medico-chirurgical service proper, the pharmacy, the *contabilità* (or whole book-keeping function of the Red Cross), the stores of linen and other necessaries, the kitchen, and every detail apt to be put *en évidence* in a campaign, were all in full exercise from day

Digitized by Google

to day. At Aquila His Majesty King Humbert paid the hospital a special visit. For more than an hour he made a minute inspection of every branch of the service, and on taking leave expressed his high satisfaction with the efficiency he had witnessed. His Excellency Signor Mocenni, the Minister of War, as well as the Director-General of the manœuvres, the foreign military representatives, and the general officers present at Aquila, also visited the hospital and put on record their sense of the completeness, promptitude, and effect manifested in the service as a whole. In fact, Count Della Somaglia, the president of the Italian Red Cross, received from the War Minister a telegram, which I am authorised to give textually: "The officers and *personnel* of the Red Cross were of signal service during the grand manœuvres, and to you I express my fullest sense of satisfaction. The scientific knowledge and practical skill of the effective *personnel* were alike admirable.—The War Minister, MOCENNI."

Sept. 17th.

CANADA.

(FROM OUR OWN CORRESPONDENT.)

The Dominion Medical Association.

WHAT the British Medical Association is to Great Britain the Dominion Medical Association is to the profession of this colony; and whilst its gatherings are not as large, perhaps, as those of the Ontario Association, which has met for some years past annually in Toronto, yet the influence of the former association must be of greater benefit to the profession at large. The interchange of ideas which happens at the annual gathering of representative men from the Atlantic to the Pacific will in the near future result in a levelling of those barriers erected by prejudicial legislation which prevent the interprovincial exchange of diplomas and act as a deterrent to the settlement of graduates of one province in any of the other geographical divisions of our Dominion—a fact which is to be greatly deplored when we have a population equal in number only to that of London and scattered over such a vast extent of country. It is, however, in regard to the effect of these annual meetings in various portions of Canada upon the raising of the professional standard and presenting to the medical world the crystals of our professional thought that I would refer, and to this end I take pleasure in presenting a brief account of the recent session held in the city of Kingston. This, the twenty-eighth annual convention, was presided over by Dr. W. Bayard, St. John's, New Brunswick, who delivered the Presidential address at the afternoon session, held on Aug. 28th. It comprised a review of the advancement of medicine in this country, and a demand that better recognition should be given by the public and the State to the members of our profession, that the salaries of those in State institutions should be commensurate with the duties, and that local boards of health should possess medical members. Speaking of the effects of alcohol, he affirmed that prohibition was not a success, and favoured the establishment by the Government of inebriate asylums, the maintenance being obtained from the revenue at present derived from the licence. Our much-lauded educational system was referred to, and the caution given that the same should not be pressed to the sacrifice of health, which, I fear, alas, is too often the tendency at present. In moving the adoption of the address Sir James Grant (Ottawa) claimed that the general standard of education in this country was too high for ordinary avocations, and he thought that common-sense was educated out of people. The Address in Surgery was delivered by Dr. J. H. Cameron, Professor of Clinical Surgery, Toronto, whilst that in Medicine was given by Dr. Farrell (Halifax, N.S.). Dr. Buller's (Montreal, P.Q.) paper on Removal of Membrana Tympani and Ossicles (illustrated) was a most interesting one. Dr. B. C. McKenzie's paper on Physical Training and Development as a Therapeutic Measure was discussed at some length by Drs. L. A. and R. H. Sayre (New York) and Sir W. Hingston and Dr. Roddick (Montreal), as also was the paper of Dr. A. Lapthorn Smith (Montreal), on What is the Best Treatment for Retroversion of the Uterus. Dr. A. J. McCosh (New York) discussed at some length the Operative Treatment of Injuries of the Head. Perhaps one of the most instructive features of the meeting was the skin [illegible] taken part in by Dr. L. Duncan Bulkeley and Dr. Robinson (New York), Dr. Graham (Toronto), and Dr. Shepard (Montreal). Of the business dealt with by the Association the most important was that relating to interprovincial registration. The report of the committee, as presented by Dr. Roddick (Montreal), was as follows:—

"The committee appointed at the last meeting of the association to look into the question of inter-provincial registration, composed of the following—Sir James Grant, Dr. Cameron, and Dr. Pyne (from Ontario); Sir William Hingston, Dr. Roddick, Dr. Marciel, Dr. Beausoliel, Dr. Cholette, and Dr. Parke (from Quebec); Dr. Christie and Dr. White (from New Brunswick); Dr. Farrell and Dr. Muir (from Nova Scotia); and Dr. Warburton (from Prince Edward Island)—would beg leave to express regret that by the system which at present obtains a graduate in medicine entitled to practise in one province is not free to exercise his functions in all the provinces of this large and sparsely settled Dominion; that this condition of things prevents the names of medical practitioners in this Dominion being placed on the British register, becoming thereby British practitioners, a boon which the Council of the Medical Association of Great Britain (*sic*) has more than once signified its willingness to grant; with the end in view that it is, therefore, considered most desirable that a uniform standard of matriculation, a uniform standard of education, and a uniform standard of examination for the whole Dominion be established in order to effect this purpose."

Dr. James Thorburn (Toronto) was elected president for 1896. The Association was received by the citizens of Kingston in a most hospitable manner, the trip to the far-famed Thousand Islands being, perhaps, the most enjoyable feature of the entertainments.

New Official Medical Organ.

For some little time past the official journal of the Medical Councils of Ontario, British Columbia, and North-west Territory has been the *Ontario Medical Journal;* in July last it became absorbed by the *Dominion Medical Monthly*, the new journal being published under the two names jointly. There is little room for congratulation on the appearance, journalistic and otherwise, of this outcome of amalgamation.

Medical Council of Ontario.

The late meeting of the Council calls for little comment, except that the proceedings have been wordy, and therefore prolonged beyond their usual length. The Council, which for the past three years has not exacted the annual fee of two dollars from practitioners, has found itself compelled to enforce the payment this year and to call upon the members for the arrears of those years. This will, I fear, meet with opposition from many of the members. I cannot help feeling that the Council should impose a fee of sufficient amount upon first registration, and put an end to this vexatious system of requiring two dollars yearly.

Sept. 10th.

AUSTRALIA.

(FROM OUR OWN CORRESPONDENT.)

Medical Practice in Victoria.

AT the last meeting of the Victorian Branch of the British Medical Association Dr. W. L. Mullen read a paper in which he reviewed the position of the profession in the Colony of Victoria. Up to about ten years ago the colony was a most excellent field for medical practice. A practitioner had simply to start in a suburban or country district and keep himself respectable, and successful practice came to him. It was quite a usual thing to make an income of £1500 per annum after a couple of years' practice. Now all is altered, and from a twofold cause—the general depression of trade and the fact that the rate of increase of medical practitioners is about ten times greater than the rate of increase of the population. During the last ten years there has been a steady diminution in the remuneration of medical work of all kinds. The rate allowed by lodges has been reduced, the salaries of resident medical officers in public institutions has been lowered almost to nothing, fees have fallen, and private practice has been diminished by the competition of the sixpenny dispensaries and the abuse of hospitals. These sixpenny dispensaries are comparatively a new institution in the colony, are largely on the increase, and are becoming a serious evil. They are the private property of the practitioner, who employs a paid agent to tout for patients and collect the fees. The members join when they like and leave when they like; they regard the medical man as a mere tradesman and as their paid servant, out of whom they must get as much as possible for their money. The medical man, on the other hand, gives as little as possible, and the practice is apt to be carried on in a perfunctory and even jeopardous manner. The lodges also are introducing a system of combining in a district and employing a

Digitized by Google

practitioner who is to be allowed lodge patients and nothing else at a fixed income. Dr. Mullen expresses the opinion that the downward tendency in the profession will continue, and hazards the guess that while individual excellence will enable a few men to maintain a high standard of remuneration, the average practitioner, after paying the expenses of carrying on his profession, cannot expect to have more than a taxable income of from £300 to £600 per annum for his private and family maintenance, and that the less amount will be the more general. It is desirable that these facts about medical practice in the colony should be well known in Great Britain, that practitioners there may know what to expect if they come here to further overcrowd the profession in a country where the ratio of medical men to population is as high, and the struggle for existence as keen, as anywhere in the world.

Irregular Medical Practice in New South Wales.

A somewhat remarkable communication was recently laid on the table of the Legislative Council of New South Wales, relating in much detail the methods adopted by certain quack establishments in Sidney. It appears that the business was really conducted by a layman, a shrewd American, who lived in luxury on the proceeds. With him was associated a medical man, who practically simply lent his name and saw a few patients. The greater part of the business was done by correspondence, the extent of which was such as to keep eleven clerks continuously employed in copying stereotyped letters, and the communication is evidently made by someone who has been a clerk in the establishment. The business was very extensively advertised and a book was also circulated. The advertisements and the book induced sufferers, real and imaginary, to write for further information and for cure for £1 as advertised, but in so doing they generally made confidential statements which they would not like made public, and which prevented exposure when they subsequently found they had been duped. They were then told by another stereotyped letter that their case was very serious and required prolonged treatment at exorbitant rates, and subsequently they received further stereotyped letters with directions for treatment and diet. The letters are all given in the communication, the whole of which is further evidence of the extreme gullibility of the public.

Snakebite.

The difference of opinion which exists in the colonies as to the efficacy of the various methods advocated for the treatment of snakebite probably arises from the want of scientific accuracy in observing and recording cases. A paper on this subject in the July number of the *Australasian Medical Gazette*, by Dr. W. C. C. Macdonald, shows very clearly how easily mistakes may be made. He points out that in very few of the recorded cases is the snake that is supposed to have bitten the patient scientifically identified, and yet harmless and venomous snakes are constantly confounded by the general public. Another important point absent from a large number of reports of cases is a description of the appearance of the bitten part, although Dr. Macdonald states that it has been abundantly proved in his own experience that a poisonous snake may inflict a bite from which no dangerous results will ensue. In order that it may inflict a fatal bite the snake must deliberately seize the part with both jaws and hold on for a definite period, and accordingly will leave marks of the teeth of the lower jaw. The part also presents a chewed appearance and is distinctly œdematous and often ecchymosed, while there is a continuous weeping from the fang punctures. Dr. Macdonald records several illustrative cases in support of his statements, and says that during the last eleven years he has seen over sixty cases of bites from various kinds of snakes, and of these only six died. Eight exhibited signs of poisoning but recovered; the rest were either incomplete bites or bites from non-venomous snakes. Three cases are recorded in detail when the snakes were fully identified, the marks of a complete bite characteristic, and the patients died in spite of repeated injections of strychnine. He concludes that strychnine is useless when a lethal dose of snake poison has been injected, and he has noticed nothing in its effects, such as strengthening of the pulse, that could not be produced by other and less dangerous stimulants. There is a distinct tolerance of strychnine by a snake-poisoned patient, and there is danger if a person has been bitten by a non-venomous snake, and is indiscriminately and largely dosed with strychnine, that dangerous and even fatal results might follow from the drug. Dr. Macdonald is of opinion that if ligature was promptly applied, other parts scarified and vigorously sucked, no symptoms dangerous to life will follow the bite of Australian snakes.

Deaths in the Profession.

By the death of Paul Howard MacGillivray, M.A., LL.D., M.R.C.S., F.L.S., the profession in Victoria has lost one of its most scientific members. He was the son of Dr. MacGillivray, at one time Professor of Natural History in Marischal College, Aberdeen, and afterwards Curator of the Museum of the Royal College of Surgeons, Edinburgh. He thus early acquired an interest in science, which he retained to the last, his researches on Polyzoa being well known. Force of circumstance drove him into the medical profession to earn his livelihood, and he has been associated with Bendigo as its leading surgeon for nearly forty years. He was a very modest, retiring man, most scrupulously honourable in all his actions, and enjoyed the complete confidence of his professional brethren. Besides his contributions to natural science he wrote many papers on medical subjects, and was among the first in Australia to study the subject of hydatid disease. In 1874 Mr. MacGillivray was elected President of the Medical Society of Victoria, and four years ago the University of Aberdeen conferred upon him the honorary degree of LL.D., a distinction his father had received fifty years before.

The death of Louis Ralston Huxtable, M.B. Edin., of College-street, Sydney, at the early age of thirty-nine, carries a sad shock to his many friends and admirers. Dr. Huxtable had just reached a high position in his profession. He was honorary physician to the Sydney Hospital, to the Sick Children's Hospital, and to the Walker Convalescent Home. For the last three years he had been honorary secretary to the New South Wales Branch of the British Medical Association, and was mainly instrumental in bringing about the arrangements for making the *Australasian Medical Gazette* the property and organ of the Branch. Dr. Huxtable was attacked by diphtheria, at first apparently not very severely. Antitoxin was injected, and he appeared to improve, but pneumonia set in and proved rapidly fatal. He will be much missed in Sydney. He was a man of charming manner and address, well read, both medically and generally, and he took a most enthusiastic interest in promoting the welfare of the profession.

Obituary.

JOHN MAKINSON FOX, M.R.C.S., L.S.A.

MUCH regret is felt at the death of Mr. John Makinson Fox, the late medical officer of health for Mid-Cheshire. He had been out of health for some time, and died a few days ago from pneumonia. He was in his sixty-fourth year, and had held his last appointment for nearly eighteen years. Previously to this he was medical officer for the Cockermouth combined sanitary district. He did much to improve the sanitary condition of Mid-Cheshire, where, indeed, much improvement was needed. New sewage schemes have been introduced, improved water-supplies obtained, and better provision made for the burial of the dead. He was a man of kindly, generous disposition, somewhat impulsive in speech and energetic in action, and earnest in his endeavours to promote public health. Having the gift of picturesque language, he often used it freely in condemnation of the sanitary misdeeds of neighbouring authorities, and especially in the case of Manchester and the Ship Canal. But notwithstanding all this and the slight dash of eccentricity which marked his numerous letters to the papers, he was much liked personally, and his influence was most beneficial to the district under his supervision, where his genial presence will be greatly missed. It may be added that he was a great lover and a good judge of pictures, and a musician of considerable attainments.

LITERARY INTELLIGENCE. — Messrs. Sampson Low, Marston, and Company will shortly publish the first and second volumes of the "Twentieth Century Practice," being an international encyclopædia of modern medical science by the leading authorities of Europe and America. This work will be completed in twenty volumes, and will be edited by Thomas L. Stedman, M.D., of New York City.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE. The following candidates have passed the examination for degrees in Medicine and Surgery at the College of Medicine, Newcastle-upon-Tyne, being the first examination for the degree of Bachelor in Medicine:—

1. *Elementary Anatomy and Physiology, Chemistry with Chemical Physics, and Botany with Medical Botany.*—Andrew Adams Bolton and James William Hugh Boyd, College of Medicine, Newcastle-upon-Tyne; John Scott, Middlesex Hospital; and Reginald Percy Richardson, Westminster Hospital.
2. *Chemistry with Chemical Physics.*—Edwin Gilbert Emerson Arnold, M.R.C.S., L.R.C.P., St. Thomas's Hospital; Ernest Castleigh Bailey, King's College Hospital; and Thomas Streatfeild, M.R.C.S., L.R.C.P., University College Hospital, London.
3. *Chemistry with Chemical Physics, and Botany with Medical Botany.*—John Henry Martin, College of Medicine, Newcastle-upon-Tyne.

The following candidates have satisfied the examiners under the new regulations:—

1. *Elementary Anatomy and Biology, Chemistry, and Physics.*—*Honours, First Class:* James Milligan, College of Medicine, Newcastle-upon-Tyne. *Honours, Second Class:* Edward Gofton, James Muirhead, Norman Christian Bailes, Norcliffe Roberts, and Harold Ben Fawcus, College of Medicine, Newcastle-upon-Tyne; William Sisam, Mason College, Birmingham; and John Tyrer Johnson, College of Medicine, Newcastle-upon-Tyne. *Pass List:* George Oswald Morrell Dickenson, Richard Henderson Garbutt, William John Harrison, and Charles Thomas Holmes, College of Medicine, Newcastle upon-Tyne; and William Johnston Symes, Sheffield School of Medicine.
2. *—Elementary Anatomy and Biology.*—Laurence James Blandford and Clifford Harold Brookes, College of Medicine, Newcastle-upon-Tyne; Edleton Harvey Cooke, St. Thomas's Hospital; Joseph James French, Arthur Hines, Eliot Swainston, and Thomas Blandford Watson, College of Medicine, Newcastle-upon-Tyne.
3. *—Chemistry and Physics.*—John Rutherford Halliday, London Hospital; Ernest Inman, College of Medicine, Newcastle-upon-Tyne; Ralph Albert Rogers Lankester, University College, London; John Macfadyen, College of Medicine, Newcastle-upon-Tyne; Robert Fletcher Moorshead, Bristol Medical School; Archibald Cameron Ney, Guy Brougham Picton, John Ernest Sidgwick, and David Henderson Weir, College of Medicine, Newcastle-upon-Tyne.
4. *—Physics.*—Allan Mackie Garnock Walker, College of Medicine, Newcastle-upon-Tyne.
5. *—Elementary Anatomy, Chemistry, and Physics.*—Ralph Harry Vincent, St. Bartholomew's Hospital.

THE Chair of Pathology in the Faculty of the Jefferson Medical College in Philadelphia is vacant.

THE salary of Mr. Stanley Kirton as medical officer for Leigh has recently been raised by the guardians of the Rochford Union from £15 to £25 a year. He has also received the Local Government Board's award for successful vaccination.

THE NANSEN EXPEDITION.—A feeling of hopeful expectancy has been aroused, especially among those interested in Arctic exploration, by the intelligence that Dr. Nansen's vessel, the *Fram*, may perhaps be making her way back to civilisation. The news comes from a Danish trading station in Greenland, where it has been reported that a three-masted ship corresponding to her description was seen by Eskimos last July firmly embedded in drift ice and somewhat to the southward of 66° N. latitude. Dr. Nansen's brother has thereupon published a letter stating that the explorer, when setting out in July, 1893, was of opinion that he could not return in less than three years. As this limit approaches, the public anxiety with regard to the fate of the expedition will not be confined to Norway, but will be general throughout Europe and America.

BEQUESTS TO HOSPITALS.—The late Mr. Thomas Chatfield Clarke, President of the Surveyors' Institute, has bequeathed £200 to the University College Hospital, London, and £100 to the Royal Isle of Wight Infirmary, Ryde, Isle of Wight.—The late Mr. John Alexander, of the firm of Messrs. Wm. Baird and Co., has bequeathed £30,000 to Coatbridge for the purpose of erecting a hospital there.—Mr. D. Sheriff Jackson, formerly of Bowden, has bequeathed £5000 to the Hospital for Incurables, Mauldeth Hall, Manchester.—Mr. Joseph Huntley, late of Kendrick-road, Reading, has bequeathed £500 to the Hospital, Reading, and £200 each to the Reading Dispensary, the London Temperance Hospital, and the North-Eastern Hospital for Sick Children, London.—The late Sir Joseph D. Weston of Clifton-road, Bristol, has bequeathed £500 each to the Bristol Royal Infirmary and the Bristol General Hospital, £250 to the Children's Hospital, St. Michael's-hill, Bristol, and £50 to the Bristol Eye Hospital.

THE PECULIAR PEOPLE.—Eccentric beliefs and observances have a remarkable faculty of survival even when they are confined to isolated individuals. If they happen to be such that their votaries may now and then take concerted action and make public display of their fatuity the unreasoning sympathies of sensation-seekers are easily enlisted in favour of a movement supported by the seeming force of numbers and enthusiasm. The strange sect which calls itself the Peculiar People realises these conditions to some extent, and has just been acquiring a transient local prominence in connexion with its annual harvest thanksgiving celebrations. These visionaries, who affect certain peculiarities of costume and demeanour, are found chiefly in the east of London and in the county of Essex, and are known to the general public mainly by their objection to medical treatment in sickness and by their implicit confidence in "faith-healing," aided by the "laying on of hands." The thanksgiving ceremonies have been well attended by excursionists, whose presence has enabled the proceedings to be carried out on an extensive scale by "Elder" Tansley's party at Chelmsford and "Bishop" Harrod's adherents at Southend. The observances and even the prejudices of a pietist community deserve respect when they are inoffensive and have the additional merit of sincerity, but it is impossible to avoid condemning a system which inflicts needless hardships on helpless sufferers and endangers a crowded neighbourhood by performing fanciful exercises over infectious cases which ought to be treated in an infectious hospital.

THE BRITISH ASSOCIATION.—A paper on the National Value of Organised Labour and Coöperation amongst Women was read on Tuesday, at Ipswich, before the Economic Section of the British Association, by Mrs. Bedford Fenwick. She quoted statistics to show the large and increasing extent to which women are now engaged in every department of labour, and pointed out that hitherto they had not attempted to any marked degree to combine and coöperate amongst themselves. She showed that the results which had been achieved by the Royal British Nurses' Association illustrated how valuable such combinations amongst women would be, not only for the individual assistance of the workers, but also for the general improvement of their methods of technical education and work. She considered the non-formation or the non-success of women's societies was largely due to the want of a central and controlling organisation, and showed how such a body could assist in the development of many industries amongst women which are at present greatly neglected. She ascribed much of the present agricultural depression to the diminished part now taken by women in dairy farming, poultry rearing, and other farm employments, and showed that for such produce alone this country last month paid more than two millions sterling to foreign nations. She pointed out the incalculable value of the home work performed by women, and quoted figures and calculations to show that an improved knowledge of dietetic, domestic, and hygienic matters amongst the women of the industrial classes would effect a national economy of at least £50,000,000 sterling per annum. Mrs. Bedford Fenwick described the constitution of a national council of women which is now being formed for the United Kingdom, with similar objects to those which national councils of women have been organised to undertake in the United States and in other countries. The council is to be divided into four main divisions—industrial, social, political, and professional—each division being constituted of a number of sections, and each section being composed of representatives of societies engaged in its special department of work.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information, suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

AIKEN, A., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer for the Maguiresbridge Dispensary District of the Lisnaskea Union.

BATTLE, E. WHARMBY, M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Manchester Royal Infirmary.

COBY, G. C., M.R.C.S. Eng., has been appointed a Government Medical Officer and Vaccinator for the district of Bingara, New South Wales.

Digitized by Google

CRAN, R. D., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Manchester Royal Infirmary.

EMBLING, H.A., M.B., Ch.B. Melb., L.F.P.S. Glas., L.R.C.P. Edin., has been appointed Surgeon-Major on the Victorian Militia Medical Staff, Victoria, Australia.

FARMER, P.W., M.B. Melb., has been appointed Honorary Anæsthetist to the Melbourne Women's Hospital, Victoria, Australia.

HALL, J. P., M.B., Ch.B.Vict., M.R.C.S., L.R.C.P. Lond., has been appointed House Surgeon to the Manchester Royal Infirmary.

HILLIER, R. J., L.R.C.P. Lond., M.R.C.S., has been appointed Senior House Surgeon to the West Ham Hospital, vice S. R. Blake, resigned.

HISLOP, PATRICK W., M.B., M.S. Edin., has been appointed a Public Vaccinator for the district of Geraldine, New Zealand.

HISLOP, WALTER, M.B. New Zeal., has been appointed a Public Vaccinator for the district of Lower Hutt, New Zealand.

HODGES, G., M.B., M.S. Edin., has been appointed a Public Vaccinator for the district of Manuherikia, New Zealand.

JAMIESON, SYDNEY, M.B., Ch.M. Edin., L.R.C.P. Lond., M.R.C.S., has been appointed Honorary Pathologist to the Hospital for Sick Children, Glebe, New South Wales.

KELLY, C. BRUCE, M.B. and M.C. Edin., has been appointed Senior House Surgeon to the Cumberland Infirmary, Carlisle.

KERING, J. D., M.D., M.Ch. Irel., has been appointed Medical Officer for the Treeton Sanitary District of the Rotherham Union.

LYNCH, A. F. A., M.B., Ch.B. Adel., has been appointed a Public Vaccinator for Moonta, South Australia.

MACDONNELL, L. G. A., M.B., B.Ch. Dubl., has been appointed Surgeon to the Hospital at Herberton, Queensland.

MCLEOD, C. G., M.B., C.M., L.R.C.P., L.R.C.S. Edin., has been appointed Honorary Ophthalmic Surgeon, to the Hospital for Sick Children, Glebe, New South Wales.

MONK, H. G. H., M.R.C.S., has been appointed Medical Officer of Health for the Borough of Leicester, vice Priestley, resigned.

MOORE, F. C., M.Sc., M.B., Ch.B. Vict., has been appointed House Surgeon to the Manchester Royal Infirmary.

MUIR, I. M. M., M.B., Ch.M. Glasg., has been appointed Health Officer for Wynyard, Tasmania.

NUNES H.F., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Clun Sanitary District of the Clun Union.

PINNIFER, WALTER A., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Brighton Provident Dispensary, vice Humphreys, resigned.

SAMSON, HENRY A., M.B., Ch.B. Melb., has been appointed Medical Superintendent at the Ballarat Lunatic Asylum, Victoria, Australia.

SCANLAN, CHAS. E. F., M.B., Ch.M. Glasg., has been appointed a Public Vaccinator for the District of Lower Hutt, New Zealand.

SCOTT, JOHN M., M.B. Melb., has been appointed a Health Officer for the Shire of Meredith, Victoria, Australia.

SHARMAN, MARK, M.B. Glasg., M.R.C.S. Eng., has been appointed Divisional Surgeon to the Herts County Constabulary.

SHARPLES, W. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer of Health by the Castleton District Council.

SHUTER, RICHARD E., M.B., Ch.B. Melb., has been appointed a Public Vaccinator at Port Augusta, South Australia.

SOUTHEY, A. J., M.R.C.S., has been appointed Medical Officer by the Slough Urban District Council.

STEEN, R. N., M.B. Lond., has been appointed House Physician to St. Mary's Hospital, W.

STEPHENS, SAML., M.R.C.S. Eng., has been appointed a Government Medical Officer and Vaccinator for the district of Walcha, New South Wales.

STEWART, JOHN, L.K.Q.C.P., L.R.C.S. Irel., has been appointed a Health Officer for the Walhalla Shire, Victoria, Australia.

SWAINSON, J. A., B.A. Cantab., L.R.C.P., L.R.C.S. Edin., L.F.P.S.G., L.M., has been appointed House Surgeon to the Hulme Dispensary, Manchester.

TAGGART, J. SCOTT, M.B., Ch.B. Vict., has been appointed House Physician to the Manchester Royal Infirmary.

TUXFORD, A., M.D. Edin., has been appointed Medical Officer of Health for the Boston Rural and Urban Districts, and Port, vice Clegg.

WARRINGTON, R. J., M.R.C.S., L.R.C.P. Lond., has been appointed House Physician to the Manchester Royal Infirmary.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton.—House Surgeon. Salary, £80 per annum, with board, lodging, and washing.

Births, Marriages and Deaths.

BIRTHS.

ALSTON.—On Sept. 11th, at Ardmore, Isleworth, the residence of her father, the wife of W. Evelyn Alston, B.A., M.B., B.C. Cantab., of a daughter.

BATTISCOMBE.—On Sept. 15th, at Sandlings, St. Mary Cray, Kent, the wife of C. G. Battiscombe, M.B., C.M. Aberd., of a daughter.

CASE.—On Sept. 10th, at Denmark House, Caister-on-Sea, Norfolk, the wife of William Case, M.R.C.S.E., late of 34, Westbourne-road, London, N., of a son.

CATTELL.—On Sept. 17th, at Hereford-square, South Kensington, the wife of George Trew Cattell, L.R.C.P. Lond., M.R.C.S., of a daughter.

GOURLAY.—On Sept. 13th, at Kincraig, Southend-on-Sea, the wife of Frederick Gourlay, M.D. Edin., of a son.

LONG.—On Sept. 9th, at Greenodd, Ulverston, Lancashire, the wife of Frank T. Long, M.R.C.S., L.R.C.P., of a son.

MARSDEN.—On Sept. 16th, at Burscough-street, Ormskirk, the wife of H. H. Marsden, L.K.Q.C.P. Irel., M.R.C.S., of a daughter.

TATE.—On Aug. 24th, 1895, at Simla, the wife of Surgeon-Major Alan E. Tate, Army Medical Staff, of a son.

MARRIAGES.

BROOKS—CHURCHILL.—On Sept. 18th, at Central Hall, Wimbledon, Jabez Pratt Brooks, M.R.C.S., L.S.A., of Queen-street, Wolverhampton, second son of R. W. T. Brooks, M.R.C.S., L.S.A., of Tollington-park, London, to Edith, second daughter of John Churchill, of Westfield, The Downs, Wimbledon.

CARDEW—MOORE.—On Sept. 11th, at St. Margaret's, Lee, H. Boyd Cardew, M.R.C.S., L.R.C.P. Lond., elder son of Major-General H. Cardew, late R.A., of Lee Park, Blackheath, to Agnes, third daughter of Mr. T. Moore, F.R.C.S., of Lee-terrace, Blackheath.

COVEY—STANTON.—On Sept 18th, at Holy Trinity Church, Millbrook, Southampton, by the Rev. Studholme Wilson, Rector of the parish, assisted by the Rev. T. W. H. Jacob, Vicar of Shirley, Edward Alan Rustat, eldest son of Charles Edward Covey, Esq., of the Lindens, Alresford, Hants, to Milborough Christiana, only child of T. Harrison Stanton, Esq., of Newlands, Millbrook, Southampton, and of Philips Heath, Stockbridge, Hants.

DONALDSON—HARRISON.—On Sept. 17th, at St. Michael and All Angles', North Kensington, Tom Campbell Donaldson, M.D., of Harlington, Middlesex, to Kathleen Emma, elder daughter of H. A. Harrison, Esq., J. P., of Doghurst, Hounslow.

ELLIS—MANDERS.—On Sept. 11th, at St. Saviour's, Tor, Torquay, Surgeon-Major Philip Mackay Ellis, fourth son of the late John Ellis, of Chudleigh, to Gertrude Septima, third daughter of the late Major Manders, formerly of the 6th Dragoon Guards (Carabineers).

HARRIS—HOWE.—On Sept. 11th, at St. John's Church, Monkstown, by the Rev. S. Howe (brother of the bride), assisted by the Rev. H. Hawkins, William James Harris, M.B., M.A., F.R.C.S., of Shaftesbury, Dorset, to Kathleen Emily, eldest daughter of the late Lieut.-Colonel Wm. Howe, of Monkstown, County Cork

LUCAS—PELLY.—On Sept. 17th, at St. Mildred's, Lee, Kent, Richard Clement Lucas, B.S., M.B., F.R.C.S., of 50, Wimpole-street, W., and of Oaklands, Midhurst, Sussex, to Kathleen, younger daughter of the late Surgeon-General Saville M. Pelly, C.B.

SIMPSON—SHARPE.—On Sept. 11th, at St. John's, Richmond, Surrey, Alexander Simpson, M.D. Aberd., of Whittingham, Preston, to Alice, youngest daughter of the late John Sharpe, of Barnes, Surrey.

SPENCER—MYLIUS.—On Sept. 12th, at the parish church, Hampstead, Matthew Henry Spencer, M.A., M.D. Cantab., of Maxilla-gardens, North Kensington, W., to Augusta Fanny Mylius, younger daughter of the late Rev. Frederick Henry Mylius, Rector of Eldon, Warwickshire.

DEATHS.

FOX.—On Sept. 12th, of pneumonia, at his residence, The Grove, Lymm, Cheshire, John Makinson Fox, M.R.C.S., Medical Officer of Health for Mid Cheshire, aged sixty-three years.

WATERHOUSE.—On Sept. 18th, at Maltby Grange, near Rotherham, Yorks, Lucy Blanche, eldest daughter of John Hodgson Waterhouse, M.D.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

ANNOUNCEMENTS REGARDING MEDICAL MEN IN THE LAY PRESS.

OUR attention has been called by more than one correspondent to an announcement in the daily press of the return to London of a consulting physician (his full address being given) after the enjoyment of a holiday. It is also pointed out that in the same issue of a newspaper in which is the announcement in question the following notice appears: "All society and fashionable Paragraphs inserted in ———, except those relating to official incidents, will be charged at a minimum rate of one guinea for two lines; each succeeding line 10s. 6d. additional." We are not so uncharitable as to draw the same inference as does one correspondent, and prefer to look on the announcement as the cruel work of a perfervid and injudicious friend. But such paragraphs should be disclaimed; for if a medical man, be he a consultant or be he a general practitioner, permits his name thus to be published without protest, he serves, we venture to say, neither his own real interests nor those of the profession to which he belongs.

L. W. P. will find a list of the principal appointments held by medical men on page 20 of the Medical Directory. A letter to either of the Departments should bring him the information he requires.

FEES FOR NOTIFICATION.

To the Editors of THE LANCET.

SIRS,—In a town in which the Notification of Diseases Act is in operation an out-door case of diphtheria is under the attendance of the house surgeon of the local infirmary. A consultation with one of the staff is requested and held. Subsequently, however, the case passes into the hands of another practitioner. All three medical men forward the usual certificate, but the local authorities have notified their intention to pay for one only. Can you refer to any legal decision bearing on such a case? I am, Sirs, yours truly,

Sept. 16th, 1895. Y. Z.

*** If our correspondent will refer to THE LANCET of May 4th, 1895, p. 1130, he will find the information he desires.—ED. L.

UNITED BROTHERS-IN-LAW AND MEDICAL ADVERTISEMENT.

ONE of the most curious customs of certain barbarous nations brought to light at the recent meeting of the British Association, and alluded to in another column, is known by the name of avoidance, and leads the mother-in-law and the son-in-law of a family to avoid each other. Very different is the case of the brothers-in-law in the paragraph below from the *Portsmouth Evening News*, which is so delicious in its mixture of family affection, church influence, and medical puffing that we give it in its entirety. We cannot say how far the dignity of Congregational churches will be advanced by such paragraphs, but they are certainly not in accordance with the dignity of the medical profession and call for Mr. Leadbeater's strong repudiation.

> "Dr. Thomas Leadbeater of Bethnal-green, who is about to take up his residence in East Southsea on account of the health of his family, is a brother-in-law of the Rev. J. Stockwell Watts, who has just accepted the pastorate of Victoria-road Congregational Church. The fact of their settling in Southsea at the same time is but a repetition of the previous coincidence of Dr. Leadbeater's commencing practice in Bethnal-green just at the time that Mr. Stockwell Watts entered upon his second pastorate in that district. Dr. Leadbeater, who had so successful a career at the London Hospital that he was pressed to become the house physician there, but declined, has since had considerable experience both as a private practitioner and at the North-West London Throat and Ear Hospital."

Messrs. Baillière, Tindall, and Cox.—With regard to the first part of their letter our correspondents are referred to THE LANCET of Aug. 24th, 1895, p. 510. The book has been received, and will be noticed in due time.

Naze.—Our correspondent's suggestion is, we think, unnecessary.

GUARDIANS AND MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—I shall be very glad of your opinion—or, if possible, an authoritative answer—to the following. About a fortnight ago I attended a man aged eighty-four years, a parish patient (I may say I am the district medical officer). The man was very ill, suffering from intestinal obstruction. He was living in one room by himself, with no one attending on him regularly. He had relatives (although he was a "parish" patient), who were fairly well-to-do, and who visited him during his illness, but stated that they could not attend to him. Under these circumstances I wrote an order to the overseers, stating that the man required a woman to go in and see after him. This order was not for a *nurse:* in the order I stated that a woman (named) had before "gone in and done for" him, and I recommended her re-engagement. The overseers (three) have lately been appointed, and for the first time. They refused to act on this order or recommendation; they waited five days, till the relieving officer visited the village, and then laid the matter before him. He told them that the only thing they could do was to order the man's removal to the union. As the patient was apparently dying this would have been impossible. Will you inform me whether the overseers are bound to act on my orders or not. One overseer tells me he will not act on my order in a like case should it occur again. I am perfectly willing to be held responsible by the guardians in a matter of this sort; but if overseers are to use their personal knowledge and feeling, it seems to me that it is useless for a medical officer to give any orders at all. The overseers based their reasons for refusal on the following grounds: (1) that they had no power to act in such a case, and (2) that the patient's relatives were able to pay for an attendant. I told the overseers that the second reason had nothing to do with themselves—that if the woman were supplied the guardians could afterwards order the relatives to refund the cost. The relieving officer lives five miles away, only visiting the village once a week. I may say that I intend writing to the guardians about the matter, but I would like to have your opinion before so doing. I am, Sirs, yours faithfully,

Sept. 14th, 1895. C. S. K.

*** It is at the discretion of the overseer (unless he gets an order from a justice of the peace) whether he acts or not, as in the absence of the relieving officer he may be held accountable for relief wrongly ordered. In the case under consideration the relieving officer ought to have been communicated with and an order for a nurse given or sent to him by the medical officer. We should not recommend writing to the guardians about the conduct of the overseer.—ED. L.

OBSTETRIC ENGAGEMENTS.

Vexed.—Our correspondent may be misinformed. He should assume the integrity of the engagement till the confinement happens. After that, and in the absence of any formal intimation to the contrary, he would have a claim for his fee.

Rheostat might obtain the desired information from one of the following firms.—Miller and Woods, Gray's-inn-road; Coxeter, Grafton-street, Gower-street; Schall, Wigmore-street.

Digitized by Google

THE "REUNION" OF MEDICINE.

General Practitioner.—Our correspondent finds in the discussion on the Reunion of Christendom a suggestion that there is also schism in medicine needing to be healed. We recognise his liberal sentiment and we share it. But there are some reunions that would be greater evils than disunion. This is certainly so in Christendom, and not less clearly so in medicine. The homœopaths isolate themselves by adopting an exclusive theory of medicine, which, after a hundred years and in the broadest age of medicine, is as far off recognition as it ever was. It is permissible for a medical man to read homœopathic literature and attend homœopathic congresses, or to do anything he pleases to arrive at a knowledge of the system.

T. O. E.—The kind brevity of our correspondent's communication does slightly interfere with its clearness at one or two points; but we venture to make the following general answer to his inquiries. It is very awkward and, indeed, scarcely permissible during a vacancy and with an election pending to require radical alterations in the rules of an institution. Notice of such requirement should be given in the interval of elections and when no personal questions can be involved. The committee were at fault in not answering promptly A's inquiry. Still, we think it would have been better for A to have allowed the election to take its course. C acted with indecision, but with obvious sincerity. We think this answer covers all the inquiries of our correspondent.

Mr. P. E. Davies.—THE LANCET, Sept. 7th, 1895, p. 605. Univ. Brussels.

HUMANE BEARING-REIN.

To the Editors of THE LANCET.

SIRS,—As I have frequently noticed your expressions of opinion condemning the bearing-rein for horses, you will doubtless be glad to know that by a very simple modification of the old pattern perfect freedom of all neck movements of the horse has been obtained. This patent is one which has been used by me for some time, and consists partly of leather and partly of indiarubber, and gives sufficient support to keep the head up, at the same time allowing of all movements. For horses that cannot be driven without a bearing-rein this removes all objections. It can be obtained of the inventor, Mr. E. Pullen, Portland-road, Hove, Sussex. I am, Sirs, yours faithfully,

Sept. 18th, 1895. A HORSE'S FRIEND.

MEDICAL TESTIMONIALS OF QUACK REMEDIES.

IT seems incredible that registered medical men should give testimonials in favour of the wares of bone-setters and other quacks. The following cutting from the *Grimsby News* would seem to prove the contrary, but we are sure that Dr. Albert E. Curtis will be able to promptly repudiate the use of his name:—

> "Notice.—J. Bromfield, bone-setter, 54, Lister-street, Hull. The only manufacturer of 'Death to Suffering.' What the medical profession says: 'I have great pleasure in testifying to efficacious effect of "Death to Suffering." I have used it in several cases of chronic rheumatism and sprained joints with very great success, and I have no doubt that in cases of struma and other allied diseases it would be most beneficial; also for cyclists and athletes who are suffering from sprains and stiff joints.'—Dr. Albert E. Curtis, M.B., C.M., 95½, Waverley-street, Hull, Nov. 4th, 1893."

Horseflesh asks: "Could any reader of THE LANCET recommend a book on the more common defects in horses? Not one to do away with the services of the veterinary surgeon, but to enable one to pick out a horse that would be worth going before a veterinary surgeon."

PRACTICE IN SOUTH AFRICA.

To the Editors of THE LANCET.

SIRS,—If any reader of THE LANCET would give some particulars about South African practice, and also say if there be a medical journal published there, and its name, he would much oblige,

Yours faithfully,

Sept. 18th, 1895. SCOT.

THE SURGICAL AID SOCIETY AND QUACK ADVERTISEMENTS.

A REMARKABLE advertisement is sent us from the advertising pages of the report of the Surgical Aid Society for 1894, setting forth the prodigious curative powers of "Odo-Magnetic Treatment," whatever that may be. Surely this is not a place for quack advertisements. We appeal to the Society and to its medical officers to refuse such means of adding to their funds.

Ahroustam.—If the person in question practises as an apothecary the Society of Apothecaries might prosecute, but if he does not assume any false title he is not committing any legal offence under the Medical Acts. He cannot, of course, if unqualified, recover for attendance.

MEDICAL ADVERTISING IN WEST HAM.

THE following is sent us as a specimen (alleged to be distributed wholesale) of medical advertising in West Ham. We appeal to Mr. Bringloe to consider whether such advertisements are likely to advance the respect of the public for the profession.

> "Dispensary, Clifton House, 90, Church-street, West Ham. Hours: Morning, 9 to 12; Evening, 6 to 9; Sundays, 9 to 12. Advice and Medicine, 6*d*. Visit (including Medicine), 1*s*. Midwifery and Vaccination. Dr. Bringloe, L.F.P.S.G., L.M."

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

METEOROLOGICAL READINGS.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

During the week marked copies of the following newspapers have been received:—*Brighton Gazette, Halifax Guardian, Eastern Morning News, Dundee Courier, Midland Counties Express, Weekly Standard (Blackburn), Scotsman, Western Morning News, Kilburn Post, Bradford Observer, Walsall Advertiser, Northern Echo, Manchester Guardian, Irish Times, Bristol Mercury, City Press, Yorkshire Post, Brighton Herald, Leeds Mercury, Sanitary Record, The News, Liverpool Daily Post, Times of India, Builder, Pioneer Mail, Shipping Gazette, Architect, Galignani Messenger, Grimsby News, Bournemouth Visitors' Directory, Local Government Chronicle, Science Siftings, Mining Journal, Brixtonian, Reading Mercury, West Middlesex Standard, Weekly Free Press and Aberdeen Herald, Hertfordshire Mercury, Courrier de la Presse, Shrewsbury Chronicle, Hawick Express, Guy's Hospital Gazette, Local Government Journal, Surrey Advertiser, Montrose Review, Rochdale Observer, Rotherham Advertiser, Fife Herald, Craven Herald, South London Press, Swindon Advertiser, Le Temps, Somerset City Herald, Banffshire Advertiser, Grantham Journal, Citizen, Loughborough Examiner, Evening Telegraph (Dundee), &c., &c.*

A Clinical Lecture

ON

A CASE OF FOREIGN BODY IMPACTED FOR FORTY-SIX DAYS IN THE LEFT BRONCHUS; OPERATION; RECOVERY.[1]

BY JOHN H. MORGAN, F.R.C.S. ENG.,

SURGEON TO CHARING-CROSS HOSPITAL AND THE HOSPITAL FOR SICK CHILDREN, GREAT ORMOND STREET.

GENTLEMEN,—Among the many casualties to which you may be summoned there is none which calls for more care, more thought or consideration, and often for more prompt and decided action, than the entrance of a foreign body into the air passages. Not only may the immediate consequences be dangerous and even fatal, but the subsequent and often remote contingencies may be of the gravest peril. The nature of the foreign body may have much to do with the results that follow its entrance into any part of the respiratory tract, and to enumerate a few of the many substances that have passed beyond the epiglottis and have been drawn downward in a sudden and ill-guarded inspiratory effort will be almost sufficient to illustrate some of the subsequent occurrences of such an accident. The more common amongst these are perhaps articles in the shape of food, which, being in the mouth, are drawn in by a strong and sudden inspiration while the epiglottis is off its guard, the glottis expanded and the larynx quiescent, such as portions of unmasticated food, plum and cherry stones, seeds, ears of grass, pieces of bone, &c. Teeth, artificial and natural, also have not infrequently been the cause of serious danger by becoming impacted in some portion of the tract, and other articles, such as shells, buttons, and pieces of money, which should not have been in the mouth at all, are usually drawn in during talking or laughing, or as the result of a sudden and unexpected blow or jerk which has caused the patient to gasp and thus draw the substance into the windpipe. Other articles, such as whistles, portions of trumpets, puff-darts, &c., have been drawn in by the inspiratory effort made preparatory to the expiratory one, which would produce sound from the former or effect the expulsion of the latter. Liquids, when bland and free from irritating properties, are often inhaled but are quickly and easily expelled; but blood or chloroform which may enter the trachea during operations may be followed by serious after results, the one by its coagulation in the bronchi and the other by its irritant properties. There are very many other articles which have been found to enter the air passages and give rise to trouble, but the enumeration that I have given will serve to illustrate what I wish you to regard. The consequences of such an accident will often call for such immediate action on your part that you have no time for other thought, but as often as not you may have to consider what will be the further changes in the nature of the substance or in what position it may possibly be arrested, either temporarily or permanently. For instance, portions of food, a pea, or a bean will be sure to swell, and thus become larger after a short sojourn in any part of the passage. On the other hand, a bullet or a shot, a bead or a coin, will not alter in consistence, but will by its weight fall to the lowest portion of the tube which its size will allow it to enter, and will not easily be induced to alter its position. Pieces of glass or china may by their angularity become fixed by penetrating to some extent the mucous membrane, or the point of a pin or needle or a puff-dart may pass through the trachea and cause ulceration of an important vessel. In many instances the foreign body, by completely obstructing the larynx or by setting up violent spasm, will cause almost immediate death; but in those cases where you have time to reflect you will have to consider, in the first place, whether there is a foreign body in the air passage at all, and, secondly, in what part of the tract it is lodged. With regard to the first question you must bear in mind that the substance may have entered the larynx and have been coughed up and ejected or even swallowed, although the irritation may continue and spasmodic cough may recur for some time afterwards. Again, it is not infrequent that substances, generally of the nature of food, so obstruct the pharynx or upper part of the œsophagus as to excite all the symptoms that would arise from their presence in the air passages, and the passing of a bougie down the œsophagus may be needed to determine this fact. Again, if the history is not distinct the symptoms may be due to an attack of acute laryngitis, or croup, or laryngismus, or the pressure of a tumour upon the recurrent laryngeal nerve. As regards the second question, you will be aided in your judgment of the probable situation in which the offending body may lie by an inspection of a duplicate. Thus, a pea or a cherry stone may by their lightness be carried up and down at each effort to cough, and at any moment may come into contact with the under surface of the vocal chords and excite a fatal spasm. Therefore, whenever possible obtain a duplicate, particularly if it should happen to be a gold coin, and consider the situation in which it is most likely to be arrested.

The symptoms which will make you suspect that there is really present in the air passages something in the nature of a foreign substance are violent and spasmodic cough, causing intense distress and a feeling of suffocation, more or less lividity of the face, and intense congestion of the veins of the neck. This may pass off and be succeeded by a period of ease of greater or less duration, to be succeeded again by the recurrent cough and dyspnœa. During this period you may have time to consider the positions in which the foreign body may most likely lie. In the larynx even large bodies, such as food or artificial teeth, may lie below the epiglottis, and after the first attack—which, however, is often fatal—may become impacted and allow time for further action. Smaller and lighter bodies may become fixed in the rima or ventricle of the larynx, where their pressure will generally be manifested by frequent attacks of spasm and by alteration of the voice, with a sense of discomfort and even of pain. Here the laryngoscope may afford you material aid. With the assistance of a solution of cocaine painted over the back of the tongue and pharynx a view may be obtained of the larynx, and the foreign body may be seen and in some instances extracted with proper forceps. But even if the body can be seen by this method it may often be necessary to perform tracheotomy, or even to divide the cricoid cartilage and extract the body either through the wound or through the mouth. Time, however, may not permit even of these deliberate proceedings, and to save life it may be necessary at once to perform laryngotomy and then to take measures for the removal of the irritant substance. When possible chloroform should be given on account of its allaying spasm and allowing of greater deliberation. But should the substance pass the vocal cords where will you expect that it may be arrested? This will depend greatly upon its nature. If it be heavy or of such a material that it swells by absorption of fluid it will sooner or later become fixed in some division of the bronchi, but if it be light it may lie for a time in the trachea, but shift its position by reason of coughing, and, coming in contact with the chords, will cause recurrent spasm and dyspnœa of a very serious nature. Here again tracheotomy is required at a very early period, and even if the substance cannot be extracted by forceps or expelled by the patient's own efforts, aided as these may be by inversion and succussion, there is no need to fear immediate danger, because, however severe the spasms, breathing can be safely carried on through the opening in the trachea. Sometimes from the nature of the substance it may become fixed in a part of the trachea, where it will rest for a long period without causing much distress. In one case that occurred at the Hospital for Sick Children a small piece of chicken bone forked at one end was found in the trachea below the vocal chords. In another child a piece of china was supposed to have been swallowed in August, 1894. Pain, cough, and vomiting of blood ensued immediately. She was taken to a hospital and an instrument passed, but nothing was found. She improved until several weeks later, when she was admitted to the Hospital for Sick Children on Nov. 2nd, and remained there for a month, but was readmitted a few days later on account of recurrence of a bad attack of dyspnœa. There was occasional stridor, but there were no obvious signs in the lungs. The history and the earlier symptoms pointed to the probability of something being impacted in the œsophagus, but upon examination by the laryngoscope it was thought that something could be seen posteriorly below the vocal

[1] This case was under the care of Dr. J. Mitchell Bruce and that of the lecturer.

Digitized by Google

chords, and on Dec. 18th I performed a high tracheotomy, when a triangular shaped piece of glass of pink colour and with sharp edges was at once expelled through the opening. The wound was sutured, and the child made a rapid recovery. Probably the case of the celebrated engineer Brunel is familiar to most of you, since it appears in every text-book, and it illustrates the fact that a coin such as a half-sovereign may lie in the trachea, but need not necessarily obstruct entirely the passage of air into the bronchi, and may act as a sort of valve, but may easily shift its position. In his case tracheotomy undoubtedly saved life, but the coin was eventually ejected from the mouth, where its effect upon the vocal chords could not produce suffocation, by reason of the lower opening into the trachea. Now the case which has induced me to bring this subject before you is an instance of the progress of a foreign body still further into the air passage, and the notes which I shall read you will give you a very good account of the symptoms which indicate, and which follow, such an event as the complete obstruction of a large bronchus, in this instance the left, by an adventitious substance. You know that the right bronchus is somewhat the larger of the two and also that the septum at the subdivision of the trachea is slightly to the left of the median line, and thus is explained the fact that foreign bodies more frequently pass into the right than into the left division of the trachea.

A healthy girl aged eight years and nine months was admitted under the care of Dr. Mitchell Bruce on Sept. 25th, 1894 Three weeks previously, whilst sucking a plum-stone which she had previously cracked, a portion of the stone fell back and, as was supposed, was swallowed. Immediately she complained of pain in her neck, and she was given a crust of bread with a view of removing it. Next day she was seen by a medical man who gave her some medicine and stood her on her head in hope of dislodging the stone. This is not a form of treatment which I should advise you to follow in similar cases unless you are perfectly prepared with all the apparatus necessary for tracheotomy. At that time, and since, she is stated to have complained of pain on the right side of the heart. Poultices were applied and constantly renewed with a view to relieve the pain, and the child was kept in bed for three weeks, during which time she took very little food. She was unable to sit up, but slept well, except when the cough troubled her, which it usually did about 4 A.M. On admission she appeared fairly well nourished. The temperature was 99·6° F. She had slight paroxysms of coughing both day and night. The left side of the chest was flattened, chiefly over the second and fifth ribs, and the movements of this side of the chest were deficient, the interspaces being sucked in during inspiration. Vocal fremitus was greatly diminished, especially below the level of the third rib. The apex beat was felt in the fifth interspace half an inch external to the nipple. The whole of the left side of the chest was dull excepting over the left of the sternum, and this dulness extended over the whole of the left lung posteriorly. The right side was hyper-resonant. On auscultation some breath sounds were heard under the left clavicle which were lost about the third interspace, and some feeble breath sounds were audible behind in the supra-scapular region, below which all was dull. On Oct. 4th, after consultation, it was decided to attempt the removal of the foreign body by operation. The patient, after struggling violently without ill effect, was anæsthetised with chloroform. The colour and breathing were good. Mr. Waterhouse made an incision in the mid-line from the cricoid cartilage down almost to the interclavicular notch. The trachea was exposed and a scalpel passed through between the third and fourth rings from below upwards well below the level of the isthmus. No mucus escaped, but a small amount of blood which entered the opening was expelled. In spite of the inversion of the patient, with vigorous stimulus to the back, the obstructing body remained *in situ*. A bent wire, with looped extremity downwards, was passed down the left bronchus, but without at first discovering any obstacle to its further passage. A double looped strand of silver wire was then passed, with the result that the object sought was distinctly felt. On each of several attempts muco-purulent secretion was brought away on the instrument, and a small quantity was expelled through the opening after each trial. On attempting to pass the little finger the child became distressed, the veins of the neck becoming distended and turgescent. The child was allowed to partially recover consciousness and the laryngeal reflex was then excited with a feather. The breathing became very spasmodic and violent, but without the effect of expelling the foreign body. At no time during the operation was the child greatly distressed. A large oval tracheotomy tube was tied in with tapes, and horsehair stitches above and below drew the skin incision together. During the ensuing night the child was in some distress, but she was relieved on substituting a Parker's tube, which was removed at intervals, but did not become clogged with mucus. During the next few days there was a good deal of cough and mucous expectoration mixed with some greenish-yellow pus, but in no great quantity. I saw the child in consultation with Dr. Bruce and Mr. Waterhouse, and it was decided to defer further treatment until the signs of bronchitis had subsided. On Oct. 19th the child seemed in a favourable condition for further proceedings. Chloroform and afterwards ether were administered. Inversion was first tried and cough was then excited by a feather passed down the trachea, but no effect was produced upon the position of the foreign body. A long probe, slightly bent, was then passed down the left bronchus, and a hard substance was distinctly felt at a distance of about five inches and a half from the lower margin of the tracheotomy wound. The wound was then held open by retractors, and a long pair of forceps, curved for the last inch of their length, was passed down the left bronchus, but the contact of the retractors making it difficult to be sure of the causation of any foreign body these were removed, and on again carefully introducing the forceps the hard substance was felt, the forceps carefully opened and closed, with the result that the foreign body was at once withdrawn through the wound. This was found to be a part (nearly half) of an irregularly broken plum-stone, which had been impacted with its apex downwards, and had been seized by the edge of the broader broken surface. The wound was left with only a guard wetted with carbolic lotion. During the following night there was but little cough, but a considerable quantity of sero-sanguineous fluid escaped from the edges of the wound. This continued for a day or two, but gradually diminished and very shortly ceased and the wound closed. The temperature never rose above the normal.

From experiments kindly made by Dr. Batten, registrar to the Hospital for Sick Children, Great Ormond-street, on the cadaver of a child about the same age and height it appeared that the body must have lodged, just as described in the case reported by Dr. Cheadle and Mr. T. Smith,[2] at that portion of the left bronchus where it bifurcates into its two main divisions and below the branch which passes to the upper portion of the left lung, and the surgical aspects of this case are almost identical with the one described by them except for the very much longer period during which the lung had been obstructed. In their case the operation was performed on the eighteenth day and in the case now described on the forty-sixth day after impaction, the ages of the two children being nearly identical and their recovery being equally complete and satisfactory. This is by no means the least interesting feature of the case. How to explain the circumstance that a large proportion of the right lung can remain for so long a period inert and entirely or almost entirely deprived of all functional activity, and then resume its functions apparently without drawback, are questions which must be left for a physiologist to solve.

RUPTURES OF THE PANCREAS: THEIR RELATION TO PANCREATIC CYSTS, WITH SOME REMARKS UPON TREATMENT.[1]

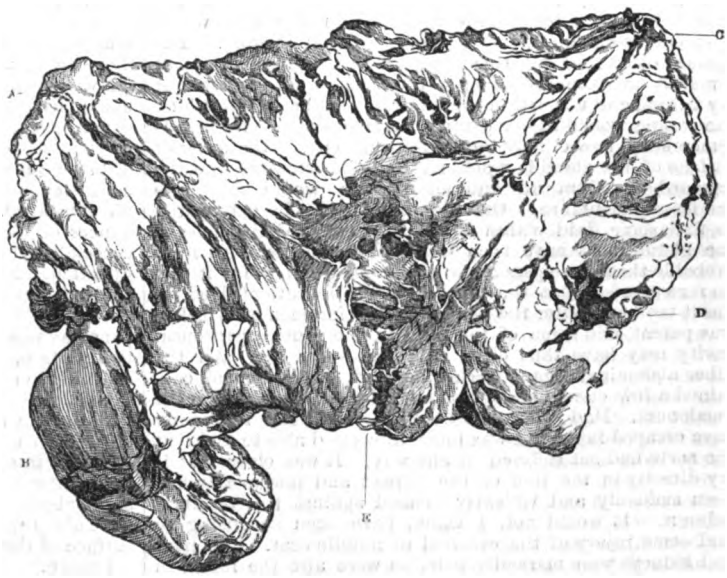
BY R. F. C. LEITH, M.B., C.M., F.R.C.P. EDIN., &c.,
LECTURER ON PATHOLOGY AT THE SCHOOL OF MEDICINE, EDINBURGH; PATHOLOGIST TO THE ROYAL INFIRMARY, EDINBURGH; EXAMINER IN PATHOLOGY AT THE GLASGOW UNIVERSITY, ETC.

INJURIES of the pancreas are rare. The size, shape, and anatomical position of this organ are in the main responsible for the comparative immunity which it enjoys. Being from 8 in. to 9 in. long, 1 in. broad, and somewhat strap-shaped, it lies transversely across the posterior abdominal wall at

[2] Transactions of the Royal Medical and Chirurgical Society, vol. lxxi.

[1] A paper read before the Medico-Chirurgical Society of Edinburgh on July 3rd, 1895.

Digitized by Google



the level of the first lumbar vertebra, the tail being a little higher than the head. This corresponds pretty nearly to a transverse line drawn across the anterior abdominal wall about 3 in. above the umbilicus. It will thus be obvious that blows or injuries received in front must be directed over a very limited area indeed in order to reach it; and not only so, but their force must be expended more or less directly backwards and not obliquely upwards or downwards, and that, too, about the middle line, so as to crush the organ against the unyielding vertebral column. Not even all such blows will succeed in injuring the organ, for it is deeply placed, being protected in front by the anterior abdominal walls, the stomach, the lesser omental sac, and the ascending layer of the transverse mesocolon. Posteriorly it is also, though less effectually, protected by certain soft structures which to a certain extent act as buffers between it and the more rigid bony framework. These are from right to left the portal vein, the inferior vena cava, the two crura of the diaphragm on either side of the aorta, with the root of the superior mesenteric artery and the left suprarenal capsule and kidney. The bony framework of the chest completely protects it from violence directed from behind, and hence we find only instances of injury resulting from violence received in front. There is some reason to believe that it may be slightly injured in cases where the force has not been expended directly over it in the middle line, but towards the left side or even with a direction from below upwards; but in order to effect any serious laceration of the gland substance the violence must be inflicted not only in the middle line and directed backwards, but must be of very considerable severity. As the neighbouring organs—the liver, spleen, stomach (especially if full), and kidneys—are all more exposed, and thus more liable to suffer, it follows that such a rupture of the pancreas, uncomplicated with rupture in any other organ, is not likely to be met with. This is amply demonstrated by our experience of the cases which have unfortunately proved fatal. In these the injury to the gland substance has generally been great. Of the more fortunate cases we cannot speak so positively, as in the absence of an exploratory laparotomy we must remain more or less in the dark as to the precise nature of the lesions. I propose to consider the cases under two divisions: (1) those in which a fatal issue followed early upon the injury, and (2) the milder cases, in which the immediate results of the injury were apparently temporary or slight and quickly recovered from, and in which the main evidence of pancreatic involvement rests on the subsequent formation of a pancreatic cyst.

1. — CASES IN WHICH A FATAL ISSUE FOLLOWED EARLY UPON THE INJURY.

I know of only 9 cases altogether, of which 7 have been previously recorded. Of the other 2, one was received into the Royal Infirmary, Edinburgh, and the other, particulars of which have been kindly sent to me by Dr. Goldmann, into the Surgical Hospital at Freiburg in Baden. In only 2 of these 9 cases is it expressly mentioned that no other organ than the pancreas was injured. In the remaining 7 other serious injuries were present—viz., rupture of the lung in 1, of the spleen in another, of the duodenum in a third, and fracture of ribs, along with other internal injuries such as rupture of the liver, kidney, or spleen, in the other 4.

CASE 1. — A boy aged four years was playing one forenoon with some companions near his father's horse and cart in the infirmary grounds. In the temporary absence of the father they had been teasing the horse, when it suddenly kicked out, striking the lad violently in the pit of the stomach with its off hind foot. He fell forcibly against the wheel of the cart, but picked himself up, apparently more frightened than hurt, and with the help of his companions climbed up into the cart. His father returned shortly after and learned what had happened, but did not think seriously of it and kept the child with him until he went for his dinner. Shortly afterwards the boy was not looking well. He complained of a numbness in his left arm, which he was unable to move. His father, fearing that the arm was broken, carried him to the Royal Infirmary, Edinburgh, where he was admitted into Ward 9 under the care of Professor Annandale, to whose kindness I am indebted for permission to refer to the case. The left humerus was found to be fractured transversely in its lower third, but there were no signs of any other injury. The head, chest, and abdomen showed no bruises and pressure elicited no pain. Later in the afternoon the patient did not look so well. He was evidently suffering from shock and pain, and obscure symptoms of some abdominal mischief began to appear. His condition became more grave as the evening came on. The shock deepened towards collapse, and although it was fairly certain that there was a serious abdominal lesion the symptoms and signs were too indefinite and diffuse and the general condition too serious to render an exploratory laparotomy advisable. He gradually sank and died about ten hours from the time of receiving the blow.

Necropsy.—This was made by me about fourteen hours after death. The usual rigidity and lividity were observed. There was a bruised appearance around the lower part of the left upper arm, which showed the usual displacement of a fracture of the lower third of the humerus. There were no other marks of violence and no bruising or discolouration anywhere upon the body. On opening the abdomen a quantity of fluid, about a pint, was seen lying freely in the peritoneal cavity among the intestinal coils. It was clear and dark-brown in colour, and had a peculiarly pungent but not fetid odour. The general peritoneal surface showed a certain amount of injection and slight loss of gloss, but there was no hæmorrhage. On raising up the great omentum with the transverse colon nothing further was observed except the appearance of a very slight amount of yellowish fluid between the intestinal coils just below the transverse mesocolon. On gently displacing the more superficial coils it became more plentiful and was evidently specially located posteriorly in this position. This yellowish fluid had slightly granular, cheesy-looking material in it closely resembling the contents usually found in the stomach when it contains partially digested milk. It suggested a rupture of the duodenum in this position, and I presently found one close to the termination of the third part. The amount of the escaped contents showed that this part of the gut had been fairly full at the time of the injury. This would favour its rupture. Indeed, I think it may safely be said that subcutaneous rupture of the collapsed bowel really never occurs. I have seen it follow a perforating wound, but not a contusion. It will be remembered that this is one of the commonest sites of

Showing the rupture in the pancreas and its peritoneal covering. The parts are in the natural position, as seen from the front, looking slightly downwards. A, Splenic flexure of colon. B, Spleen. C, Hepatic flexure of colon. D, Points to a tear in the ascending layer of the transverse mesocolon in a line with K. E, Rupture in the pancreas.

Digitized by Google

intestinal rupture, for here the gut is more or less fixed, and rests upon the vertebral column. The tear in the present case was through the whole wall for about two-thirds of its circumference, the peritoneal coat still being intact in the other third. There was another small tear about three-quarters of an inch long in the mesentery of the jejunum a short distance lower down. There was very little hæmorrhage. The margins of the peritoneum in the neighbourhood of the tears showed a little infiltration with blood-clot, and there were a few petechiæ in the transverse mesocolon, but nothing further. The transverse colon was then displaced downwards and the pancreas exposed. The ascending layer of the transverse mesocolon and the underlying pancreas were both found to be torn. The rupture in the gland was a little less extensive than that in the mesentery. It ran vertically from above downwards with a slight obliquity to the right, passing through its whole thickness at its upper border, but through a part only towards the lower border. The main duct and the splenic vessels were uninjured. The line of rupture was almost directly over the aorta and on being continued through the transverse mesocolon became continuous with that in the duodenum. This was probably the line of chief impact of the horse's hoof, the organs having been crushed between it and the vertebral column. Its position in the pancreas about the junction of the right with the middle third is well seen in the preceding engraving, which is from a photograph. The ruptured ends had separated a little from one another and were infiltrated to a slight degree only with blood. There was practically no blood in the lesser omental sac, which, except for the tear already mentioned in its posterior wall, presented a perfectly normal appearance. Blood had effused from the rupture, as the retro-peritoneal cellular tissues contained a certain quantity of diffusely spread blood-clot. It might have amounted altogether to about three ounces. It passed mainly to the left above the pancreas towards the spleen, reaching its hilum and infiltrating also a little downwards. It did not pass behind the pancreas except just at the tail, where it spread itself slightly over the suprarenal capsule. The amount of hæmorrhage thus appeared to be remarkably small for such an extensive injury to the gland, and, moreover, it lay behind and not within the lesser omental sac, into which the gaping wound in the gland directly opened. When it is remembered how closely the peritoneum covers the anterior surface of the gland it would naturally be expected that the hæmorrhage from an anterior rupture would flow into the lesser omental sac. On other grounds also I was prepared to find some fluid within this sac, as many of the ducts of the gland must have been torn across, and it is at least probable that some pancreatic juice was secreted, for it will be remembered that the unfortunate little patient lived for about ten hours after the accident. The foramen of Winslow was patent, and some of the fluid in the general peritoneal cavity may have thus come from the lesser sac. All the other abdominal organs were uninjured. The stomach contained a few ounces of material similar to that seen in the duodenum. Had it been distended it might not so readily have escaped injury. I was much interested also to find that the aorta had not suffered in any way. It was clear that it lay directly in the line of the impact and presumably had been suddenly and violently pressed against the vertebral column. It would not, I think, have been surprising to find some injury of the external or middle coat. The liver and kidneys were markedly pale, as were also the lungs, in part suggesting a large rather than a small hæmorrhage. This was certainly not present. The bowel contents only showed some blood-stained mucus for about eighteen inches below the site of rupture. The cranial sinuses were congested, but the brain and its membranes were healthy.

The special points of interest in the case are the nature of the injury, the comparative absence of serious signs for some time after its infliction, their subsequent rapid onset and gravity, the absence of any marks of violence upon the abdominal wall and of pain, the large amount of fluid in the peritoneal cavity, the severity of the rupture in the pancreas, and the smallness in amount and the anatomical position of the hæmorrhage. If the shock and collapse had been due to the injury acting directly upon the solar plexus or more indirectly through the nerves of the pancreas and peritoneum their onset would have been expected to have been practically immediate, and one is therefore led to suggest that they are referable rather to the changes occurring in the peritoneal cavity subsequently to the injury. The dark-coloured fluid, about one pint in amount, had probably not come from the ruptured gut, as it was different in character from that found in the neighbourhood of the tear. There remains then only the inflamed peritoneum or the torn pancreas to explain its presence. It is decidedly unusual to find such a large quantity of fluid associated with a simple early peritonitis, and it is thus quite as probable that the pancreas was responsible for some of it, at any rate. It is probable that pancreatic secretion has, under certain circumstances, a peculiarly irritating effect upon the peritoneum, and its gradual and steady escape into the general peritoneal cavity would largely explain the phenomena observed in the present case. The other points of interest will be considered in conjunction with the other cases.

CASE 2.[2]—A young man received a violent blow upon the abdomen from the fall of a heavy packing-case upon him. It is believed that the corner of the case struck him in the epigastric region. On his admission to hospital his chief symptoms pointed to abdominal hæmorrhage and intestinal obstruction. A tumour gradually formed in the mesogastrium resembling that formed by a pancreatic cyst. There were no marks of bruising externally upon the skin of the abdominal wall. The general condition of the patient was too grave to permit of laparotomy. He died a few hours after the accident. At the necropsy the pancreas was found to be transversely ruptured. Profuse hæmorrhage had occurred into the cavity of the lesser omentum and given rise to the pseudo tumour in the mesogastrium. The spleen was also lacerated. The other organs were uninjured.

CASE 3.[3]—A native of India, a male about fifty years of age, had been subjected to a somewhat curious assault. He was tied up in a sort of lithotomy position, his hands being first tied together, and his knees then forced within the area of the tied arms and secured there by a long lath passing from one side to the other through the space between the anterior aspect of the elbow and the posterior aspect of the knee. His assailant then beat him violently with a shoe on the exposed buttocks, genitals, and abdomen, and also kicked him once or twice. On being released he walked home, a distance of about one mile, supported between two persons. He was then admitted to hospital and died about eighteen hours afterwards. At the necropsy it was found that the pancreas was ruptured vertically from above downwards at its right extremity for about half its breadth. A small clot of blood was found near this, and the rest of the organ looked congested and showed extensive extravasation of blood into its substance. The abdominal cavity contained about six ounces of blood-stained fluid, and the peritoneum in places, especially the transverse mesocolon, showed considerable injection. No other lesion was found and there was no external sign of injury.

CASE 4.[4]—An adult was run over in the street. The pancreas was so crushed in its middle as to be divided into two parts opposite the spinal column. There was but little other sign of injury to the abdominal viscera.

CASE 5.[5]—A man thirty-three years of age was run over in the street by a light car going very rapidly at the time. He showed no external signs of injury. His symptoms pointed to severe internal hæmorrhage, and he died in less than two hours after the accident. The pancreas was literally smashed and embedded in coagulated blood. The spleen and kidney were also ruptured, and there was a slight tear in the under surface of the liver. Several ribs were broken.

CASE 6.[6]—An intoxicated woman was knocked down by a stage coach, which, however, did not pass over her, and she died a few hours afterwards from internal hæmorrhage. The pancreas was transversely torn across. There were other internal injuries, the liver being lacerated and several ribs broken.

CASE 7.[7]—In this case the pancreas and lung were both injured.

CASE 8.[8]—A woman was run over by a coach and died within a few hours. The pancreas was completely torn in two and embedded in a large mass of semi-fluid blood. Several ribs were fractured and the liver was ruptured.

CASE 9.[9]—A lad showed rupture of the pancreas and other severe injuries, which speedily proved fatal.

Edler,[10] the latest writer on this subject, could in 1887 find only 3 cases of this lesion—viz., those of Cooper, Travers, and Kuhlenkampff.[11] I have not followed him in including the last-named case, as it afforded no evidence that it was a case in point. Kuhlenkampff himself did not claim that the pancreas had been ruptured or lacerated. He believed that the severe blows which the patient had received upon the epigastric region had caused an inflammation of the pancreas, which, through resulting obstruction of the main duct, had given rise to the mesogastric cyst, which he successfully opened and drained. Senn,[12] writing a year earlier, mentioned 4 genuine cases—viz., those of Cooper, Travers, Störck, and Le Gros Clark. I have been able to add 7 cases to the 2 genuine ones of Edler and 5 to those of Senn; but even the increased knowledge thus afforded is still sufficiently meagre to make us exercise much caution in forming any general conclusions. In at least 3 of the cases the injury was caused by the patients being run over by a vehicle, and it is interesting to note that in almost the only surgical text-book in which I have found any reference to rupture of the pancreas, that of Jamain,[13] it is said that this very rare lesion is usually thus caused. A violent and sudden blow is responsible for 3 more cases.

Symptoms and signs.—Shock and collapse would seem to be the most prominent. They are usually brought about immediately by internal hæmorrhage, as in Cases 2, 5, 6, 8, and 9, but may be due to other and less obvious causes, as in Cases 1 and 3, where they developed only after a considerable interval. They are probably due more to the complications than to the pancreas. In no case have the symptoms pointed to the pancreas as the main seat of lesion. The absence of any bruising, ecchymosis, or discolouration of the skin of the abdomen, or any sign of external violence is important and not a little surprising. Its bearing upon medico-legal cases is obvious. Serious criminal assaults may be made, as in Case 3, without any outward or visible sign of injury. A similar absence is noted in Cases 1, 2, and 5, and I have several times observed it in other cases of ruptured viscera. It may almost be said to be the rule and not the exception. It may occur also in the thorax, as in the case[14] of a child run over by a cart, in which the lung was torn without any fracture of the ribs or injury to the wall of the thorax.

Diagnosis.—This is practically impossible without laparotomy. The nature of the violence, its exact site of impact and direction may make the lesion probable. It can only be verified by laparotomy. I have satisfied myself that upon the cadaver at all events the anterior surface of the pancreas can be thoroughly explored by the finger through a vertical incision about three inches long in the middle line anteriorly, or preferably a little to its left in the epigastric region. If an electric lamp be placed in the interior of a Fergusson's speculum both the pancreas and its covering peritoneum can be scrutinised.

Prognosis.—The foregoing cases were all rapidly fatal. The cause of death was internal hæmorrhage in at least five of the cases—viz., Cases 2, 5, 6, 8, and 9; but this result was in all probability more due to the complications than to the lesion in the pancreas. In Cases 1 and 3 the hæmorrhage was small in amount, and not one of the other parenchymatous organs was ruptured. It is then at least probable that the hæmorrhage from a rupture of the pancreas alone will not be severe unless the splenic artery or vein be ruptured. In themselves they need not be fatal.

Treatment.—It has already been shown that the lesion in the pancreas is rarely the only one present, and, further, that the rupture in the gland does not declare itself by any definite signs or symptoms. It follows, then, that ordinary expectant treatment (rest, ice, &c.) alone can be followed, except in the cases where an exploratory laparotomy is performed. If this be done and a rupture be discovered it should at once be treated. The hæmorrhage may be arrested by pressure and the ruptured ends brought close together by comparatively superficial sutures passing through little more than the peritoneal covering of the gland. This covering adheres so closely to the gland, without the intervention of any fatty or other tissue, that it is easy to bring the separated ends of the gland together by traction exerted alone upon the peritoneum. This procedure is, however, open to the objection that blood or pancreatic juice may collect between the ends and cause their separation again, and lead, perhaps, to cyst formation or other trouble. Senn,[15] from his experiments on animals, recommends that the ends of the ruptured gland be separately ligatured previously to such suturing. This has the advantage of effectually arresting the hæmorrhage and the outpouring of the pancreatic juices, and, further, the close approximation of the ends favours the rapid establishment of the nutrient vascular supply. He would first remove the necrosed portions of the gland. He found that ruptures treated in this way quickly healed and that there was no danger to be apprehended from the distal part of the gland, as all such physiologically separated portions of gland underwent simple atrophy and in no case led to cyst formations.

2. MILDER CASES.

It has already been seen that such evidence as can be brought forward tends to show that ruptures of the pancreas need not in themselves prove fatal, and it is quite conceivable that many such ruptures may occur, and probably have done so, in varying degree of severity in cases of abdominal injury which have been entirely recovered from. Perhaps large ruptures such as occurred in Case 1 may lead to such an extensive outpouring of pancreatic secretion, mixed with blood-clot and fragments of devitalised pancreatic tissue, that its escape through the foramen of Winslow into the general peritoneal cavity may set up a general chemical and perhaps also organismal peritonitis. Evidence on such a point is lacking, however, and it is more probable that the lesion in the gland is followed by inflammation which results in nothing more than a certain amount of cicatricial contraction, and the patient recovers entirely without the subsequent occurrence of any other trouble. Cases have been recorded in which even extensive cicatrisation of the gland existed without any suspicion of its presence during life. It is obvious, however, that other possibilities exist. There is room for other results between those two extremes. The lesion in the gland may be followed by an inflammation, not restricted to the gland itself, but spreading gradually to other tissues in its neighbourhood, and leading, perhaps long afterwards, to subsequent trouble. This supposition is further strengthened by the fact that many cases of injury received in the epigastric region have been followed, sometimes long afterwards, by the appearance of a cyst in this region, and the relation which the so-called *pancreatic cysts* bear to ruptures of the gland itself is a most interesting one. Increasing attention has been of late years paid to the subject of these cysts, and a traumatic origin has been assigned to a large proportion of the reported cases. These number, so far as I can find, altogether seventeen, and I have arranged them in chronological order in the table on the following page.

The history of the injury is most definite in these cases; moreover, the formation of the epigastric tumour followed sufficiently soon after it as in itself to be presumptive of the relationship being cause and effect. The earliest appeared ten days after and the latest eight years. In the latter it may reasonably be doubted if there was any connexion between them. It is in a measure, however, supported by two of the cases being delayed for three years and another for one year. In six the interval varied between two and four months, and in the other five between two and five weeks. It will be noticed that nine of them were more or less directly related to falls, six to blows upon the abdomen, and only two to being run over by a vehicle. It is a somewhat curious fact that all but one occurred in males, and this is probably to be accounted for by the greater liability of the male sex to injury. It might justly be brought forward, however, as an additional argument in favour of the causal nature of the injury. Granting, however, that the injury was the primary cause of the formation of the cyst, we have still to show that that injury involved the pancreas. The evidence

on this point is fairly satisfactory in several of the cases, for the fluid obtained on aspiration or evacuation of the cysts, on being submitted to analysis, gave the reactions characteristic of the pancreatic juice. In other cases the contents failed to give these reactions, and this may point to an origin altogether independent of the pancreas. It is known, however, that great changes may occur in the composition of the contents of such cysts, especially if they are

12	1891	M.	50	In lifting a heavy weight he felt something give way in the epigastric region. Shortly afterwards he had a severe fall, which "knocked his breath out."	About three or four months after began to feel pain, and later a tumour appeared.	Richardson: Boston Medical and Surgical Journal, 1891, p. 111.
13	1892	M.	38	Horse threw and stamped upon him, striking him over the upper part of the abdomen on the left side.	About three weeks.	Littlewood: THE LANCET, April 16th, 1892, and the Transactions of the Royal Medical and Chirurgical Society, 1891-92, p. 25.
14	1892	M.	20	Knocked down by a horse at a race meeting.	About three months and a half.	Lloyd: Brit. Med. Jour., vol. ii., 1892, p. 1051.
15	1892	M.	27	Thrown upon the floor and kept there for a time.	About ten days. Patient said he noticed it at once.	Ibid.
16	1894	M.	2	Run over by the wheel of a cab.	About three weeks.	J. L. Thomas: THE LANCET, March 31st, 1894.
17	1894	M.	17	Crushed between a locomotive and a truck, the buffer striking his abdomen.	About three months and a half.	W. H. Brown: THE LANCET, Jan. 6th, 1894.

of long standing, and it may be that, the connexion with the pancreas having been cut off, the pancreatic character of the fluid will be gradually lost. We are thus led to look for evidence along other lines. The most conclusive of all—viz., that derived from post-mortem examination—is of very little avail here, as of the seventeen cases just quoted only one ended fatally. The others all recovered after the cyst had been incised and drained. The fatal one—viz., No. 14 of the table—was reported by Lloyd. An enormous encysted hæmatoma was found situated behind the stomach. It contained three or four pints of dark blood containing old coagula. The folds of the lesser omentum were so altered that it was hardly possible to say how they entered into the formation of the wall of the sac. No special examination of the pancreas for injury was made. This case affords us but little if any help, and we are therefore compelled to fall back upon the domain of hypothesis and conjecture in seeking for an explanation. Kuhlenkampff [16] suggested that the injury might cause an inflammation of the gland substance, which might lead to closure of the main duct and a consequent retention cyst. Senn [17] held the same view until he found from his experiments on animals that very little distension followed obliteration of the main duct, and that, in short, any part of the gland physiologically separated from the main exit duct underwent simple atrophy. He then suggested that these cysts might have more than one mode of origin and that the hæmorrhage into them might be variously explained. He gave three main hypotheses: (1) hæmorrhage into a pre-existing pancreatic cyst; (2) parenchymatous hæmorrhage producing a cyst, followed by hæmorrhage into the cyst wall; and (3) that the hæmorrhagic cyst may originate in a dilatation of one of the vessels of the pancreas. Now the first of these does not get over the difficulty of the first formation of the cyst, and the third, while it may be said to be possible, must be regarded as rare. The second view is at once the most obvious and probable. It

[16] Loc. cit.
[17] Loc. cit., vol. xc., 1885, p. 34.

Digitized by Google

was further elaborated by Cathcart,[18] who puts it as follows: "The injury causes a laceration of the gland. This is followed by extravasation of blood, and with this is mixed the pancreatic secretion from the torn ducts. Not only is a constantly increasing fluid thus added to the original hæmatoma, but the collection of fluid probably becomes irritating in character. It will thus tend to excite the formation of a capsule around it, and by chemical irritation and tension would gradually increase in size." This view of the causation and mode of origin of these so-called pancreatic cysts is not only the most natural but also the most probable which has yet been propounded. It is so obvious that it has doubtless occurred independently to other observers. Indeed, it did so to myself, and I find that Jordan Lloyd[19] has had a similar experience. He says (apparently unaware of Senn and Cathcart having previously suggested it): "The secretions of the torn gland may be poured into the lesser omental sac with the blood, and that even if pure pancreatic juice be not irritating to the peritoneum a mixture of pancreatic juice and devitalised blood-clot may have a very different effect, and that chemical changes of a digestive kind may then be started, which may irritate the serous lining of the sac and cause it to pour out its secretions and thus gradually distend its cavity." Now, obvious and simple as this explanation is, it must be remembered that it is hypothetical and must be carefully tested before it can be accepted as being satisfactory. Before accepting it as being the mode of origin of these pancreatic cysts we must exclude the possibility of other and neighbouring structures acting as primary factors in their formation. This cannot be done, for it is found that many cases of similar cysts in this region arise apparently spontaneously. No connexion with the pancreas may be suspected until an analysis of the cyst contents suggests it. Such cases are much more numerous than those apparently of traumatic origin. Some of them may originate in retention cysts, as seemed to be the case in a woman aged thirty-five referred to by Sharkey.[20] A tumour said to have been in existence for from twelve to fifteen years was found in the left hypochondrium. It was remarkably mobile. On opening the abdomen it shot out of the wound, dragging with it the tail of the pancreas. On enucleating the cyst the pancreas bled very freely. It is at least improbable, however, that even the majority have a similar origin, and inquiry must be made if no other way is open which would still allow them to retain a connexion with the pancreas. Such a way is, perhaps, to be found in the spontaneous hæmorrhages which occasionally arise from the pancreas or suprarenal bodies. It is quite well known that hæmorrhage may take place spontaneously into and around the pancreas. It has been met with not infrequently in varying degrees of severity and standing. If recent the infiltrated parts have the dark colour of ordinary venous blood-clot, and if old they have a brown or slaty colour. Such hæmorrhages may even speedily prove fatal. Zenker[21] describes three such cases occurring in strong, healthy men and Draper[22] five somewhat similar cases. Challand,[23] Prince,[24] Gussenbauer,[25] and others have also discussed the subject. Minor cases are doubtless still more common and may result in the formation of a blood cyst. If the hæmorrhage ruptures any of the pancreatic ducts there may be a mixture of pancreatic juice as well, and hence the mode of origin of such cysts may come to closely simulate traumatic ones. Störck[26] and Parsons[27] each record a case which somewhat supports this contention. In both a sanguineous cyst connected with the pancreas was present, and the tissue of the gland was infiltrated with hæmorrhage that had taken place into its substance. The parenchymatous hæmorrhage may have been the first thing here, and may have led to the formation of the cyst, which increased by further hæmorrhage taking place from its wall. It is of course possible, though not so probable, that the cyst preceded the hæmorrhage. In some cases the hæmorrhage is more manifest in the neighbourhood of the pancreas than within the organ itself. Harris[28] mentions a case of sudden death in an alcoholic patient where the hæmorrhage was into the adjoining subjacent peritoneal tissue as well as into the pancreas; and Biggs[29] another case of a man who fell dead on coming out of a beer saloon in which he had taken a few glasses of beer. There was hæmorrhage around the pancreas and a number of minute hæmorrhages within it. I will not discuss the causes of such spontaneous hæmorrhages. The question is an obscure one. Signs of acute inflammation of the gland substance were found in some, while in others the gland was apparently quite healthy. It is not necessary, however, for the blood to come from the pancreas. It may come from the suprarenal. Virchow[30] describes a form of acute hæmorrhagic inflammation of the suprarenal capsules, and several cases of large spontaneous hæmorrhages into and around these organs have been put on record. Further, there is evidence that hæmorrhage may be found in the neighbourhood of the pancreas without having any apparent connexion with either of these glands. Rolleston[31] mentions the case of a man aged thirty in which hæmorrhage was found around the pancreas, the source of which could not be determined. It is apparent, then, that the first step in the formation of a cyst may arise in a variety of ways, and it is conceivable that such a cyst in the course of its gradual increase and extension may come to acquire a connexion with the pancreas, though it originally possessed none. Fischer[32] suggests "that a pancreatic cyst may originate as a blood effusion in the neighbourhood of the gland, it being supposed that the tension of the sanguineous effusion may cause atrophy of part of the gland substance and escape of fluid from opened ducts." He cites as a probable instance a case recorded by Merigot de Treigny,[33] where a sanguineous cyst was found adherent to the pancreas, which was atrophied at the position of contact. This anatomical connexion is certainly suggestive, but it is far from conclusive, as it is capable of explanation by other and perhaps more probable modes of origin.

So far these observations have been restricted to hæmorrhages from the region of the pancreas, but in considering the possibilities of cyst formation in this region other conditions of etiological importance should be remembered. Blood has not been present in all these cysts, even in all the traumatic ones, and as serous cysts arise in connexion with the spleen, liver, suprarenals, and even lesser omentum, it is obvious that this latter class must be taken into account when dealing with the origin of epigastric cysts. Hydronephrosis, echinococcus, retro-peritoneal dermoid cysts, or even ovarian cysts, have to be included also. The mere mentioning of most of these possible origins is all that is required for my present purpose. Their occurrence is well enough established, and the only one requiring further consideration is the lesser omentum. Its surface extent is the greatest of all the structures in the epigastric region, and if cysts can arise in it independently of any other structure it is at once obvious what a frequent source of origin it may become. It will facilitate this investigation if I first consider whether either traumatic or spontaneous cysts may arise from the peritoneum at a distance from the pancreas. I find that there is fair evidence on the subject. Godlee[34] has recorded three cases of cysts following upon injury whose origin was very possibly peritoneal. In the first, a girl aged four years, the cyst had formed on the right side of the abdomen about three weeks after she had been run over by a cab. He believed that this cyst was primarily renal, due possibly to a ruptured ureter. In the second, a man twenty-three years of age, the cyst formed on the left side and was aspirated about four weeks after the injury. In the third, a boy aged seven, the cyst formed first on the left side, and later, about eleven months after the accident, spread to the epigastric region. It was incised. These three patients recovered, and there was no special evidence, in the latter two at any rate, to connect them with any particular organ. Again, in the case recorded by Brown[35] there was reason to believe that a similar peritoneal cyst, separate from and independent of the pancreatic one,

was present as the result of an earlier injury. The evidence in support of similar peritoneal cysts arising spontaneously is still more conclusive. Terrier[36] gives the case of a man aged thirty-four years who had suffered from attacks of colic and diarrhœa for about five months previously to the detection of a swelling in the hypogastric region. This was tapped and 450 grammes of blood-stained fluid withdrawn. The cyst refilled and formed a rounded swelling reaching from the pubis to the umbilicus and to within two fingers' breadth of the iliac spines on either side. Laparotomy was performed and the cyst removed; it was about the size of a fœtal head and was apparently connected with the mesentery. It contained what looked like pure blood and its walls were of some thickness and were coated internally with fibrin. The patient recovered. Frentzel[37] records another case in a woman aged twenty where the cyst, about the size of a child's head, was situated about the middle of the right side and was very movable. It was found to lie between the layers of the mesentery and to contain sero-sanguineous fluid. The patient recovered. Simon[38] found a cyst of the great omentum in a man who died from Asiatic cholera. It was adherent above to the greater curvature of the stomach. It had thin walls and contained granular, rust-coloured blood coagula. The arteries and veins of the omentum were normal. With the exception of a few small ulcers in the colon the organs of the body appeared to be healthy.

It thus, I think, becomes clear that both traumatic and spontaneous cysts may arise from the peritoneum, and hence many of those recorded as present in the mesogastric region may be fairly enough referred to the lesser omentum as their source of origin. Thus Sutherland[39] mentions the case of a girl aged eight who was run over by a cab. Three weeks later a swelling appeared in the epigastrium, which disappeared after aspiration about five weeks after the injury. Richet[40] relates a case in a man aged forty-two who had been knocked down by an omnibus and about six months later developed a cyst in the epigastric and left hypochondriac regions. He died from peritonitis ensuing after injection of the cyst, after aspiration, with a weak cauterising fluid. The lesser omentum was occupied by a cyst limited above by the liver, below by the pancreas, and in front chiefly by the small omentum, but partly by the stomach. All the surrounding organs were healthy. Rendu,[41] Gullois,[42] and Méry[43] have recorded somewhat similar traumatic cases, in none of which could any connexion with any of the surrounding organs be detected at the necropsy, or any satisfactory explanation of the origin of the cyst be given. I might in a like manner cite instances of similar cysts of a spontaneous origin. Pomier[44] opened and drained one in the left hypochondrium. It contained 1500 grammes of purely serous fluid. It is unnecessary to multiply instances, nor is it incumbent upon me at present to explain the origin of such cysts. Rouiller[45] suggests that a sclerosis of the peritoneum of alcoholic origin first causes hæmorrhage and then a cyst; and Fischer[46] that the lesion is nervous, probably having its origin in the solar plexus. The latter holds that the hæmorrhage is not really situated within the peritoneal cavity, but between the omental or mesenteric layers. Be this as it may, however, it is obvious that they come to simulate pancreatic cysts more closely than any others, and if the record of pancreatic cysts be scrutinised it will be seen that many of them, both traumatic and spontaneous, have no real right to their name, as they had probably no connexion with the pancreas. It is not generally appreciated how many the fallacies are. Not only must we exclude the cysts of the various surrounding organs—e.g., the spleen, kidney, supra-renal, and liver—but the great body of peritoneal or retro-peritoneal cysts have also to be taken into account before it can be asserted that any cyst is of pancreatic origin. Chemical analysis and microscopic examination will indeed afford assistance in many cases, and they are of the greatest value when they give positive evidence, but when they fail to do so, as is often the case, we are not entitled thereby to exclude a pancreatic origin, as the contents of the cysts may become much altered in the course of time. Indeed, in the absence of some such direct physiological or anatomical evidence, we have no right to either assert or deny a connexion with the pancreas. In any such case the possibilities are many, and we are not entitled to do more than suggest the likelihood of its being of pancreatic origin. Its greater frequency makes this source the most probable, but it would perhaps be better not to use the term "pancreatic" as descriptive of any such doubtful cyst. The term "epigastric" is fairly distinctive and has the advantage of in no way begging the question. For prognostic and therapeutical purposes a perfectly accurate diagnosis is not, after all, so much of a desideratum, as all cases, whether pancreatic or not, seem to be equally amenable to treatment.

Treatment.—Wherever there is a collection of fluid about whose boundaries and connexions there may be some doubt, the natural tendency is to evacuate the fluid with the least possible disturbance of parts. Hence it is seen that the first procedure adopted was an emptying of the cyst by means of aspiration. Experience has shown, however, that this is both ineffectual and dangerous, as the cyst gradually refills. Attempts to secure obliteration of the cyst by means of the injection of iodine, &c., have been somewhat disastrous. A fatal peritonitis has resulted more than once—indeed, the simple aspiration itself has been followed by somewhat similar serious consequences, brought about doubtless by the rupture of the cyst walls, when thin, and the sudden escape of the contents into the peritoneal cavity. Aspiration has thus been abandoned in favour of laparotomy, which is the favourite method of treatment at the present day. The cyst is brought forward to the anterior abdominal wall and is incised and emptied. Drainage is secured by means of a pancreatic fistula, which discharges for a variable time and then heals. It was the method followed in all the seventeen cases recorded in the foregoing table of traumatic pancreatic cysts, in all of which, except one, it was successful. It has been followed with like success in many other cases. Krecke[47] says that of twenty-seven cases treated by section and drainage all recovered; and of six cases treated by dissecting out the cyst three died. The advisability of trying to dissect out the cyst is very doubtful. Excision may be easy in some cases, but it will be difficult in most, and experience does not favour its recommendation. The method of anterior incision and drainage, notwithstanding its success, is not altogether perfect. It has actually failed to cure in a few cases, and other objections may be urged against it. It is much more suitable for the somewhat movable cysts which come forward to the anterior abdominal wall. These are generally broader anteriorly than posteriorly, and are thus readily opened from the front. It is not nearly so suitable for that other division which are somewhat sessile, broader posteriorly than anteriorly and much less movable. They are not easily reached by an anterior incision, and, moreover, it is by no means easy to bring the wall forward of such a cyst to the anterior incision and thus to secure its safe evacuation. In addition, I have to urge the obvious disadvantage of the anterior incision, alike for men and women, in so far as it interferes with the natural usefulness of the abdominal walls, and provides for a drainage of the most imperfect character, allowing of a cure only after a more or less protracted period of time. Further, the possibility of the pancreatic fistula becoming permanent must not be entirely denied. Senn, in his experiments, found that it never occurred, but actual experience in the human subject does not quite bear this out. Gould,[48] indeed, mentions a case in which not only did the pancreatic fistula remain permanent, but malignant disease appeared around it. It appears to me, therefore, not only reasonable, but most advisable, to seek for some other method of reaching these cysts free from these objections. Cathcart, Littlewood, and others have spoken of the ease with which a counter-opening could be made posteriorly in these cases, and it occurred to me that they might be primarily reached and drained by a posterior operation. I thereupon verified this suggestion many times upon the cadaver. I found it much easier than I expected to cut down upon the tail of the pancreas and lesser omental sac. A vertical incision about three inches long is made at the outer border of the left rectus, beginning above at the twelfth rib. After cutting through the skin

and fascia the thin fibres of the latissimus dorsi are first recognised, and then the strong fascia at the outer border of the rectus. This is incised and the upper border of the quadratus lumborum is next seen running downwards and outwards. The finger is inserted above it and feels for the posterior surface of the kidney through the fat and cellular tissue. It then defines the position of the renal vessels. The tail of the pancreas and the postero-lateral wall of the lesser omental sac lie just above and inside them, and by inserting a probe I was able to enter the cavity of this sac, either through the mesocolon below the lower border of the pancreas or through the posterior peritoneum above this gland, at will, according to the obliquity upwards given to the probe. In no case was the suprarenal capsule or any other structure in the neighbourhood injured. When the lesser omental sac was distended with fluid fluctuation could be distinctly felt by the exploring finger working upwards above the renal vessels, and the fluid could be evacuated with ease by means of a drainage-tube made to enter the sac with the help of a director and a pair of dressing forceps. This procedure will be found to be quite as easy in cases of pancreatic cysts and probably of others in this neighbourhood. The cyst wall may be thick and thus a little difficult to penetrate, but that need not cause much trouble, while the long existent distension will have brought the cyst within more easy reach. It may even extend downwards below the line of the renal vessels, and thus be reached by the surgeon whether he goes above or below these structures. This method of reaching these cysts from behind was adopted by Mr. Cotterill with complete success in a case now under his care in the wards of the Royal Infirmary, Edinburgh. He entered the sac below the renal vessels. The patient is doing well. Others have adopted a posterior incision after an anterior one has failed. Thus Gould mentioned that in a case where the cyst was fixed and could not be brought to the surface, with a finger in the cyst he cut down behind below the twelfth rib and drained it posteriorly. The fistula rapidly closed up. A better proof could hardly be given of the advantages of the posterior incision. He would doubtless have easily reached the cyst had he tried the posterior incision at first. I would strongly advocate this method of procedure, not only because of its ease, but because of the advantages of a posterior over an anterior incision, and of the more perfect drainage and much more rapid convalescence and cure which it promises. Even if it were to fail to reach the cyst, it would in no way prejudice the success of an anterior exploration, and would, moreover, even in such a case, allow of the rapid establishment of posterior drainage.

Edinburgh.

A CASE OF ULCERATIVE ENDOCARDITIS ASSOCIATED WITH COARCTATION OF THE AORTA.

BY THOS. B. FLINT, L.R.C.P. LOND., M.R.C.S. ENG.,
SENIOR HOUSE PHYSICIAN TO THE MANCHESTER ROYAL INFIRMARY.

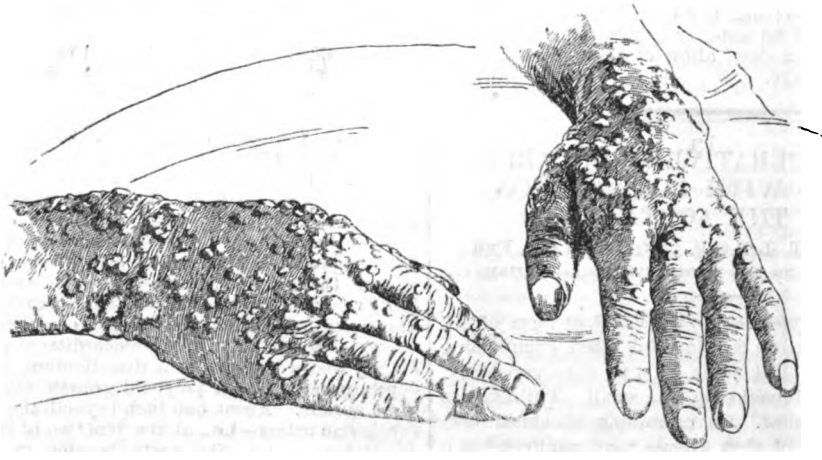
A MAN aged twenty-one came to the accident-room of the Manchester Royal Infirmary on May 20th, 1895, complaining of hæmoptysis, which had come on two days previously. The quantity of blood brought up was small. Phthisis was the first thing thought of. On examining his chest, however, no physical signs of that disease were manifest, but a double murmur heard best over the aortic area was discovered. Both systolic and diastolic murmurs were very loud and entirely replaced the heart sounds. On feeling the pulse it was found to be distinctly a "Corrigan's," and on rubbing the skin over the forehead capillary pulsation was well seen. He was admitted as an in-patient under the care of Dr. Steell. The next day a more detailed examination was made. The patient was a well-nourished man, but somewhat anæmic. On inspection it was noticed that there was marked pulsation in the supra-sternal notch and in the neck, especially the upper part. The apex beat was in the sixth left intercostal space and just outside the nipple line. On percussion the cardiac dulness extended three-quarters of an inch to the right of the mid-sternal line and four inches and a half to the left of it at a level of about one inch above the upper margin of the liver. Above, the dulness did not extend higher than the third rib. On auscultation the loud double murmur was heard as before in all four areas of the heart, replacing the sounds. When listening at the lower angle of the left scapula both murmurs could be plainly heard; but higher up, just below the scapular spine, the systolic murmur was alone heard and was remarkably loud. On looking more closely along the surface of this area where the murmur was heard the loudest it was noticed to be pulsating, and numerous tortuous arteries, some of considerable size, could be seen beating in it, and on laying the hand over it a slight thrill could be felt. The pulsating area occupied practically the subspinous fossa. On the right side a similar condition existed, but it was not so well defined as on the left. The pupils were equal, and both radial arteries gave the same tracing—a typical aortic regurgitation one. As regards the other organs, the lungs were apparently normal. The sputum was examined several times for tubercle bacilli with negative results. The liver was slightly enlarged and projected about a finger's breadth below the costal margin. The spleen was also enlarged. The urine was normal. As regards his previous history, the patient stated that he had never suffered from rheumatism or chorea, that his work was not heavy, that he had never noticed that he was short of breath, and had never had any swelling of the legs and feet. From the date of admission to the end of the second week of June the patient progressed very well. The pulse averaged about 100, the respiration was about 18 per minute, and the temperature in the morning averaged about 98·2°F. and in the evening about 100·2°. The hæmoptysis almost disappeared. During the third week of June, although the patient did not complain, it was noticed that he was getting paler and his appetite began to fail. The pulse averaged 120, the respiration 20, and the temperature in the morning 99° and in the evening 100°. On June 24th the patient complained of pain in his right side, and his temperature rose in the evening to 101·2°. The next day he coughed up a considerable quantity of blood from the lungs. He perspired profusely and vomited during the day about three pints of undigested food. There was some dulness at the base of the right lung. A distinct *bruit de galop* was heard for the first time over the cardiac region. The superficial arteries could be seen pulsating much more plainly than before, and the urine contained some albumin. He gradually became worse, his pulse-rate increasing to 132 per minute, his respiration to 54, and his temperature to 101°, and he died on the 29th from heart failure.

Necropsy.—The brain and spinal cord were not examined. The pericardium was considerably increased in extent and there was a slight increase in the amount of pericardial fluid. The heart was greatly enlarged downwards and outwards, giving to the organ almost a bovine character. The weight was 1 lb. 5 oz. The right auricle was slightly dilated. The tricuspid orifice was slightly dilated; the segments were normal. The right ventricle was dilated and greatly hypertrophied. The pulmonary artery was apparently normal. The left auricle was dilated and hypertrophied. The mitral orifice was dilated and admitted three fingers; the segments were healthy. The left ventricle was dilated and greatly hypertrophied. The aortic segments were almost completely destroyed by masses of recent ulcerative endocarditic vegetations. Immediately above the valves a diverticulum, fully one inch in depth, projected as a polypoid growth into the cavity of the right auricle. About one inch beyond the origin of the left subclavian artery—i.e., at the junction of the transverse and descending aortas—the aorta became extremely narrowed and only admitted a small probe. The contraction extended over a very inconsiderable space and was sharply defined both at its commencement and at its termination. The ductus arteriosus was obliterated and terminated at the concave portion of the aorta about one-sixteenth of an inch above its contraction. The descending thoracic and abdominal aortas were of about normal size, but the iliac and femoral vessels were smaller than usual. Coming off from the descending aorta immediately below the constriction there was an artery as large as the brachial; this proved to be the first aortic intercostal. The posterior scapular arteries were much enlarged and tortuous and anastomosed with the upper intercostal branches close to the spine. These vessels formed the pulsating area described above. The internal mammary arteries were also much enlarged. The liver was enlarged. The spleen wa

Digitized by Google

enlarged considerably. The kidneys were healthy. The left lung was normal. The lower lobe of the right lung showed pneumonic consolidation and was in the stage of red hepatisation. There was a small amount of fluid in the right pleural cavity.

Remarks.—The condition of coarctation of the aorta, although rare, is by no means unique; I have, however, never seen a case recorded in which the patient was also the subject of ulcerative endocarditis. An interesting point in the case was the close resemblance it bore to pulmonary phthisis, the temperature, down in the morning and up in the evening, being very suggestive of this, but, of course, there was the presence of the valve lesion to account for it. The patient and his mother (a very intelligent woman) were certain that he had never had rheumatic fever or chorea, nor had he suffered from any other serious ailment previously. He had never undergone severe physical exertion, and his work had always been light. Then, again, the enlargement of the spleen is worthy of note, as is also the albuminuria which came on shortly before death. The temperature, too, was always more or less raised during the whole of his stay in hospital.



Manchester.

A RARE FORM OF SKIN DISEASE FOLLOWING THE EXTERNAL APPLICATION OF IODINE LINIMENT.

BY D. ROBERTSON DOBIE, M.D. EDIN.

IN THE LANCET of Sept. 29th, 1894, appeared two very interesting articles, the one upon an epidemic skin disease occurring in public institutions, and the other upon the treatment of small-pox, two very dissimilar subjects to allude to. I am induced from a study of those to think the following case will be of interest and importance on the one hand to medical practitioners who devote their particular attention to skin affections, and on the other hand to medical officers of health, who may at any moment be consulted as to the best means of checking the spread of disease amongst a community. Dr. Henderson and I were at first in a dilemma as to what was the nature of a most suspicious eruption which made its appearance in a case under treatment in the Coldstream Cottage Hospital. The following are the history and notes of the case, and I am of opinion that, although not by any means unique, it is of sufficient rarity to make it worth recording.

On Sept. 13th, 1894, I was summoned to visit a man aged twenty-four years who had been ill for about four days with headache, lassitude, and pain in the back. I found the patient with a high temperature and double pneumonia. I ordered his immediate removal to the Coldstream Cottage Hospital, where a more thorough and complete examination as to his condition was made. His previous history may be shortly noted. After his apprenticeship he enlisted and was sent to Egypt, and when abroad he became subject to epileptic fits and was discharged on that account. He came home and found employment in various ways, feeling well and able for any amount of work. Three weeks before the present illness he went to harvest work, and continued this employment four days, when he felt unwell. He worked when he felt able, and went to bed when he felt worse. He finally gave up and came home, but did not send for medical advice until the date of admission, when he was suffering from pneumonia and symptoms of advanced renal disease. On each succeeding day the temperature averaged from 98·4° to 99° F., with an evening rise not exceeding 100·8°. The urine was highly coloured with bile, and thickly charged with albumin, fully two-thirds of a test-tube quantity. The amount ranged from seventy to eighty ounces. The usual treatment necessary for such cases was carried out with great care and his condition every day carefully noted. The consolidation of the lung became most marked, and in every respect his condition might safely be said to be improving. It is unnecessary to go into every detail, but what I wish particularly to point out in the course of the treatment was the painting of the back with dilute iodine liniment, equal in strength to the Edinburgh tincture of iodine. This was applied morning and evening from Sept. 14th to the 18th. On the 19th the patient's face was completely covered with a papular, pustular, vesicular eruption; in some parts, more particularly in the region of the ear, a bullous eruption. These pustules all over the face were discrete and confluent, forming large encrusted sores, with swelling of the eyelids, lips, nose, and ears. A copious discharge from the nostrils accompanied this. The face was increased enormously in size. At the same time a perfectly different, purely papular eruption made its appearance upon the back of the hands, wrists, and forearms. The patient experienced severe smarting and heat in the face; in other respects there was no change in his condition. My colleague and myself were at first not a little alarmed at this sudden development, more particularly when we discovered, on making inquiries, that he had been sleeping during the time he was at the farm in a bed adjoining two strangers, labourers from the county of Durham. The period of incubation of small-pox would not tally with his account of the dates, and on consulting Dr. Radcliffe Crocker's able work on "Skin Diseases" and Plate 33 of the Sydenham Society "Atlas of Skin Diseases" I discovered

that we had a case of iodide eruption. The eruption on the face in the course of four days gradually died away, leaving healthy epidermis and no scars, the scabs peeling off rapidly. The papules on the hands continued very prominent. On careful examination it was easily seen that the papilloma was a distinct epithelial growth upwards. On puncture a clear viscid fluid escaped; no pus was found in any of them. There was a well-marked red ring round the base of each, and not one had the slightest appearance of subsiding. On Sept. 27th the patient complained to the nurse in attendance of headache and chilliness all over his body. His temperature was 99·4° at 8 o'clock in the morning. At 12 o'clock he was seized with sickness, nausea,

Digitized by Google

and vomiting. A severe rigor set in, and the temperature had risen to 101°. The pulse was rapid and tumultuous. The patient became cyanosed. Respirations were rapid and stertorous. He became rapidly unconscious, with twitching of the hands and frothing at the mouth and nose. Profuse perspiration ushered in a violent convulsion. He had ten similar attacks following each other in rapid succession. These seizures were typical uræmic convulsions. Pilocarpine and venesection, baths, chloroform, &c., were all tried to alleviate his suffering and distress without success, and he died at 5.45 P.M. the same day.

Remarks.—The difficulty which surrounded the diagnosis of this most interesting case at a moment's notice will be evident at once, and several of my colleagues who were quite familiar with the early appearance of variola were startled at the eruption on the hands, wrists, and forearms, and admitted that it was an impossibility to distinguish the difference without minute examination and inspection of the fluid on puncture of the papule and a close analysis of the history of the case. There are several cases of a like nature recorded, after the internal administration of iodide of potassium, but I am unable to find any mention made of a typical, and what I should say in this case an aggravated, iodide rash, induced by the local application of the liniment to the skin of the back, which throughout remained in a healthy, unbroken condition. For a full description of the appearance and for the pathology and minute anatomy of the disease I beg to refer my readers to the account given at page 300 of Dr. Crocker's work on Skin Diseases, second edition.

Coldstream, N.B.

ROUGH NOTES ON REMEDIES.[1]

BY WILLIAM MURRAY, M.D. DURH., F.R.C.P. LOND.,

CONSULTING PHYSICIAN TO THE NEWCASTLE-ON-TYNE HOSPITAL FOR SICK CHILDREN, AND LATE LECTURER ON PHYSIOLOGY AT THE UNIVERSITY OF DURHAM.

No. IV.

MERCURY IN HEART DISEASE.

I HAVE been somewhat disappointed in the discussion at Edinburgh on cardiac stimulants, inasmuch as I see hardly any reference was made to the value of mercury in cases of heart disease. I fear that our views on this subject have not advanced of late, and the mind of the profession has not grasped the idea that mercury has a value in heart disease far beyond what may be termed its "alterative" action. The administration of this drug in cardiac dropsy and in all cases of passive congestion of the pulmonary and portal systems is as old as the hills, and we old-fashioned physicians know well enough that thirty or forty years ago no one thought of treating these conditions except by a mercurial pill followed by a saline or jalap purgative and a diuretic mixture containing digitalis. Then came the days when the diuretic mixture was changed for one of muriate or ammonio-citrate of iron with digitalis, and some of us will remember the remarkable papers of Dr. Handfield Jones on the value of this combination. Now we have come to the days of arsenic, strychnia, iodide of potassium, and a host of cardiac stimulants, together with rest and cardiac gymnastics. I expect that in all cases our remedies do but assist nature in bringing about healthy compensatory changes by preventing degeneration of the muscles and vessels of the heart and main bloodvessels. Repeated observation has convinced me that mercury possesses a value far beyond the supposed alterative nature of its action—not that it fails to relieve congested vessels by drainage or osmosis, for doubtless this lays the foundation of its further action on the heart itself, and it would fail to relieve the heart did it not eliminate biliary and other effete matter from the blood and tissues of the liver and portal system, for instance; but when due allowance has been made for these primary effects there remains strong evidence that it tells upon the heart itself. Its special benefits are exercised in cases of dilated and hypertrophied heart. By means of it the "thready," weak, rapid, and irregular pulse is made full, soft, regular, and slow, with manifest relief of such symptoms as dyspnœa, pectoral weight and tightness, and sensations of faintness. The "angina sine dolore" is often marvellously relieved and removed by two or three grains of blue pill three times a day, and the severe forms of "angina pectoris" not unfrequently disappear under its influence. While the nitrites, nitroglycerine, &c., afford temporary relief, this remedy is much more permanent in its effects. Nor need I say that to give digitalis a fair chance it is absolutely necessary to pave its way by preliminary doses of mercury and to foster its action by repeated doses. Many of the cases where digitalis, &c., fail, or seem to fail by supposed accumulation depend on this, that we are giving the digitalis without the blue pill or calomel, and it often falls to the lot of the consultant to make a great hit by inserting the mercurial into the previous treatment. Much more true is this of iron and digitalis combined. We see a patient with engorged vessels and labouring heart taking iron and digitalis much to the detriment and not to the benefit of the case—each dose is but adding fuel to the fire—energising the heart in its futile attempts to drive the blood through the engorged vascular system, and thus exhausting the organ in its hopeless struggle. We change all this by frequently repeated doses of mercury; we drain the portal system, we exosmose the water from the general vascular system, we suck up dropsical accumulations, and by pushing the drug we get hold of the heart itself and produce the slow, soft, regular, and effectual pulse, giving the digitalis or strophanthus a fair chance to come in as cardiac tonics; and at last we complete the circle by arriving at the point whence we departed with the patient in a very different condition, and we can give the iron and digitalis now with impunity—nay, with immense benefit. Let the following case speak for itself, and its quotation is the more apt as the patient came from being under the care of an eminent Edinburgh physician in the very condition I have described—viz., a dilated and hypertrophied heart goaded to excess in a useless effort by iron and digitalis.

A case of dilated and hypertrophied heart treated by 20,000 grains of blue pill; recovery from advanced cardiac dropsy followed by ten years of good health.—The patient, a hard-working man, was a Scotchman, and had all the talent, physique, and energy peculiar to his race. He gradually developed symptoms of valvular disease and dilated heart when about forty-eight years of age. He went to Edinburgh and was under treatment there for several weeks. At last he was sent home with the assurance that nothing more could be done for him. My friend, Dr. Wilson of Wallsend, was summoned to see him, and he called me in consultation on the case. We found the patient in the following condition. He was propped up in bed. His countenance was anxious, his eyes seemed to protrude from their sockets, and his face was bathed in perspiration, with a livid colour of the lips and skin. His breathing was shallow, frequent, and difficult, accompanied by a constant hacking and ineffectual cough. His pulse was hardly perceptible, irregular, and thready. The heart's action was tumultuous and irregular, the cardiac sounds were almost inaudible, and a distant murmur could be heard with both sounds at both the right and the left apex. No cardiac impulses could be felt except a wavy movement at the epigastrium. The liver was enlarged, and the abdominal cavity was distended with fluid, as were also the lower extremities and the scrotum. The pleural cavities were also occupied to a considerable extent by fluid effusion. We determined to abandon the usual cardiac stimulants and gave him two or three grains of blue pill thrice a day, and at the end of two days we gave him a smart purge of jalap. Greatly encouraged by the result, we pushed the blue pill (two to three grains three times a day) for a week or more, and during that time a steady relief of all the symptoms ensued. The countenance became placid, the tongue (before dry and brown) became moist, and the pulse more regular, full, and soft; the dropsical accumulations gradually receded, and the breathing resumed a normal character. Now was the time for digitalis—always best given on a falling tide in dropsy—and doubtless the patient owed much of his rapid recovery to the temporary and occasional use of that drug; but the staple of the treatment was the steady use of blue pill, now gradually diminished to two pills a day, and finally to a five-grain pill at bed time. To sum up the results, the man felt himself to be quite free from all his troubles in six weeks, at which date I met him in the Newcastle railway station and had the pleasure of presenting

[1] Nos. I., II., and III. of this series were published in THE LANCET of Feb. 25th and Nov. 4th, 1893, and Sept. 21st, 1895, respectively.

Digitized by Google

my convalescent to an extra-mural teacher of eminence from Edinburgh. From this time the patient resumed his duties and became a useful and active member of society.

Now the point of interest in this case is this—and I want to emphasise it—that during the next ten years the patient stuck to his blue pill every night with few intermissions, and declared that whenever he did leave it off for a few nights his heart began to trouble him and his breathing became difficult. As will be seen from the post-mortem notes, this nightly dose was in some mysterious way enabling a heart, massive with disease, to discharge its duties in such a way as to make its owner feel quite well. During the ten or eleven years of his subsequent life, Dr. Wilson calculates, he took 20,000 grains of blue pill; it never salivated him, it neither purged nor nauseated him, and it never gave his breath a touch of fetor. At last, however, his old symptoms returned, the machinery was worn out, and he died chiefly from the pressure of abdominal fluid on his enormous heart. I regret that such a case should be so roughly handled, it deserves a more accurate and detailed description, and I trust Dr. Wilson will some day give his details of it. My son, Professor George Murray, and Dr. Wilson made a post-mortem examination, of which these are the notes:—"On opening the thorax the heart was seen to be enormously enlarged, and the space occupied by it measured eight inches across and eight inches from above downwards. The lungs were displaced backwards and compressed by the enlarged heart. Heart: The right auricle was very much dilated, almost to the size of a man's fist. The walls were thickened and the muscular tissue hypertrophied. The auriculo-ventricular orifice was very much increased in size and readily admitted eight fingers at once. The tricuspid valves were much thickened and opaque. The right ventricle was much dilated and the walls thin. The left auricle was much dilated, the walls thick, and the endocardium opaque. In one part of the wall of the auricle there were two bars of calcified muscular tissue united by a crossbar of the same substance. The auriculo-ventricular opening was much constricted and hardly admitted the tip of the index-finger. The mitral valves were adherent, so that there was only a small opening like a button-hole between them. The valves were thick and rigid, but not calcified. The left ventricle was dilated, but its capacity was only about one-half that of the right ventricle. The walls were not much increased in thickness. Abdomen: The peritoneal cavity contained a considerable amount of clear fluid. The spleen showed a dense white patch of scar tissue one-fourth of an inch deep in the centre—evidently the site of a very old infarction. The surface of the liver was nodular; on section it showed dense strands of connective tissue of advanced cirrhosis."

Remarks.—I need not say that to rescue a man from the jaws of death and give him ten or eleven years of fairly good health confers on any drug a reputation. Its potency is established. We therefore ask, How does it act? Is it a cardiac tonic, stimulant, alterative, or what? Or does it act on the secondary apparatus of the circulation and the blood itself by reducing the resistance of the vessels, diminishing the volume of blood, and altering its fibrinity so as to make it circulate more freely? I think it does all these things, and at the same time it soothes the heart by purifying the blood of effete accumulations.

Newcastle-on-Tyne.

THE PREPARATION OF ANTIRABIC SERUM AND THE METHOD OF DETERMINING ITS STRENGTH.

BY PROFESSOR GUY TIZZONI AND DR. EUGENE CENTANNI.

(Concluded from page 731.)

IV.—THE ANTIRABIC SERUM AS A PROTECTIVE.

BEARING in mind the more exact methods established for the standardising of the dose of the serum and of the virus, we have proceeded to test the power of our serum by various methods of experiment. We began by seeking to determine what dose of serum injected under the skin prior to infection would be capable of preventing the action of the virus. These experiments have no direct or important bearing upon practice, inasmuch as, rabies being a disease of rare occurrence, we cannot speak of its treatment in the healthy individual before there has been any contagion whatever. From the scientific side, however, these experiments are of very great importance, and constitute the starting-point of other researches and other tests of the efficacy of the serum; one knows, in fact, that the efficacy of the serum may vary according to the time which intervenes between its introduction and the moment of infection. We can inject the serum a long time before infection—weeks or months—with the aim of determining what is the duration of the immunity conferred by it—a question which has a certain importance, as we know that one of the points which we wish to establish between the immunity given by the serum and that given by means of vaccine is whether the first has a much shorter duration; we have, therefore, in the course of these experiments dwelt on the durations of the immunity, and shall deal with them in a separate paper. The serum can also be introduced a short time before infection; this is done very frequently and is adapted to solve certain important questions. We have carried out a more extended series of experiments of this kind in order to determine the following points. 1. The relation existing between the quantity of serum introduced prophylactically and that necessary to be introduced at various periods after the occurrence of infection. These doses are very different, and form an ascending series, starting from the moment at which the infection has taken place; in the various infections this rise in dose does not proceed with equal intensity, but the degree of this increase gives us an idea of the degree of infection, and hence of the greater or lesser difficulty of curing it, according to its intensity. As regards the curative use of the antirabic serum we shall see the importance of establishing the relation between the curative and the preventive doses. 2. The relation between the different methods of injection of the serum, with a view to hastening the absorption and lessening the loss of active material. One knows that serum may be introduced by way of the peritoneum as well as by way of the veins. We have adopted a new method, the immense advantage of which over the subcutaneous method will presently be seen. 3. A means of determining the dose necessary to counteract the infection made with the canine virus and one made with the fixed virus, and hence, indirectly, to return once more to the comparison of the two viruses. 4. A method of estimating the strength of the serum.

It has already been seen how by the method of subcutaneous injection we sought to determine the best type of vaccination. We have, however, abandoned this in our latest experiments in favour of more simple and exact methods. In the following table (Table XIII.) we have collected several groups of experiments made with serum upon sheep and after various kinds of vaccinations, the serum having the power of typical serum. This serum has been introduced twenty-four hours before infection, it being injected at one single time if a small quantity was being used, and at three or four times when the quantities were much larger. Only in the latter event did the animal suffer in any way from the injection, either from a little local œdema or from some diminution of the body weight. The infection was always made beneath the dura mater, the canine virus and the fixed virus being used. (See Table XIII.)

Passing in review the experiments made with the canine virus, we find that, in presence of an infecting unit introduced into the brain, our typical serum having the value of 1 to 25,000—that is, 0·04 c.cm. (corresponding to at least a drop or to three milligrammes dry product)—is sufficient to protect a rabbit of the weight of one kilogramme; against the fixed virus the dose must be raised considerably, this being safe up to 1 in 100, according to which a rabbit of the weight of one killogramme demands at least 10 c.cm. This dose is to that with the canine virus as 250 to 1, whence one sees the great increase of activity which the virus has undergone by repeated introductions into the rabbit—an increase which appears the greater if the limit of dilution of each of these is not considered and they are taken at equal volumes. And since the fixed virus at an equal volume contains 200 more infecting units than the canine virus of mean strength (the relation between the dilution 4 in 1000 and 1 in 50), so it may be deduced that the fixed virus is 50,000 times stronger than the canine, or at least, that to protect against the infection practised with a given

Digitized by Google

weight of the one needs 50,000 times the dose which protects against an equal weight of the other. Of the other lessons which this table furnishes we shall speak later, when it will be possible to deduce them by comparison with data obtained by other methods of experiment.

V.—THE ANTIRABIC SERUM AS A CURATIVE AGENT.

From the preceding experiments it is evident that the antirabic serum, like any other protective serum, succeeded, not only in preventing the malady from invading the still intact organism, but also in cutting it short after the infection—it may be during the period of incubation, or even when the first rabid phenomena have been manifested. We were then limited to establishing the possibility of the fact, reserving to later researches the determination of the degree as we have already observed when treating of the rabbit, in the lesion of a large nervous trunk, and in the introduction of virus sufficiently concentrated, represents a form of infection certainly graver than the somewhat small bite usually met with in man. We draw particular attention to the table of the curative experiments at varying periods after infection. The serum used came from two sheep; that of one had the strength of the typical serum, that of the other had a power eight times less $\left(\frac{ST}{8}\right)$; but the calculations all referred to the typical serum. The infection was made in the usual manner—by way of the nerve with a dilution of 1 in 20, and by way of the brain with a dilution of 1 in 30, always injecting 0·13 gramme per kilogramme. Nothwithstanding that in

of this action and the relation of the various quantities of serum which might safely act during the various periods of the disease. It is not necessary to demonstrate how much attention should be given to this part of the argument, since the antirabic treatment in man being necessarily undertaken after the smallest bite the means to cut short rabies after infection and with the least quantity of serum must crown all our researches. In making this series of experiments we have principally drawn attention to the demands which the serum must satisfy in its application to man. We were therefore confined to the employment of the canine virus as the material of infection; besides experiments with subdural infection we have carried out a considerable number with infection in the sciatic nerve, which, making the infection every care, as above stated, was taken, it must not be taken for granted that in any given series of animals the multiplication of the virus proceeds directly parallel in all, and that they must at the same period of incubation always neutralise equal doses of virus. One not infrequently encounters in some one animal a somewhat more rapid development of the disease, so that, for instance, what for one animal is the tenth day represents for another the twelfth or fourteenth. (See Table XIV.)

The results displayed in Table XIV. have a marvellous regularity; a more exact application of mathematics to the measurement of complete biological phenomena could not certainly be desired. If any doubt should remain as to the efficacy and proportion of the action of the serum

Digitized by Google

this table would serve of itself alone to completely dispel it. It furnishes us with data of immense value for the application of the serum to man when bitten. We are able to establish a comparison between the preventive dose and the curative dose, and also between the curative doses themselves at various periods after the infection. We will first consider the experiments with infection in the sciatic nerve. The preventive dose established by us for the serum employed in Table XIII. is 1 in 25,000; now it is seen that no sooner do we pass from the preventive dose to the curative dose than a considerable difference arises. On the first day after the infection a dose of serum as much as five times greater is required, not, indeed, to save the animal, but merely to postpone its death. On the second day the insufficiency of that dose is made up for by another dose three times greater, and we see that to obtain positive results we must carry the dose of serum up to six times that of the protective dose. On the fourth day the dose is found to lie between five times (always insufficient—see Example 95—as in the preceding cases) and ten times (dose sufficient, see Example 96). The experiments on the eighth day are important as to number and constancy. From them it results that a dose only three times larger (Example 11) is inefficacious, and that a dose seven times larger gives an uncertain result, since in one case it is of value and in another not. The results, constantly positive, begin when we carry the dose to eight times that of the preventive (Example 110 *et seq.*). On the tenth day a dose forty-five times greater succeeds (Example 146), while on the eleventh day a dose twenty-five times greater (Example 137) is of no use, but should be a warning, as at the moment at which the injection was practised rabies, which in this animal appeared in an exceptionally rapid manner, had already developed. The following may, therefore, be taken as established, to be verified by other infections—viz., that there is an increase of the dose over the protective, but that such increase succeeds in less proportion than in the better known infections—e.g., tetanus and diphtheria. In fact, in rabies this increase for the first half of the period of incubation oscillates between six and eight times, whereas in tetanus, from the time of the infection up to the appearance of the first symptoms, a dose is required 1000 to 2000 times the strength of the protective, and in diphtheria 20 to 100 times. From what has been stated one may deduce how the dose differs during the period of incubation. While on the second day it is necessary to employ six times the protective dose, on the eighth day it suffices to push it simply to eight times; this is surprising, considering that in rabies one is not concerned with a pure intoxication by a fixed dose of poison, but with a virus which grows and spreads continually through the nervous system. From our own experiments and from those of other observers we know, in fact, that on the eighth day after infection in the sciatic nerve with the canine virus the lumbar marrow is already virulent, and it is admitted that a diffusion of the virus takes place even before the animal presents the symptoms of the disease. Adhering, nevertheless, to the often established fact of the constant relation of neutralisation between the virus and the serum, we must maintain that the multiplication of the virus during this period cannot be very considerable, and that when we undertake the treatment during the first half of the period of incubation we ought not to have to contend with very large quantities of virus; nevertheless, it cannot be too strongly recommended to commence in rabies, as in other infections, with the serum treatment as soon as possible after the disease has been contracted. After the eighth day it is perceived that the dose has to be raised much more rapidly, but that on the eleventh a multiple twenty-five times greater does not succeed. Further than that the table does not inform us. We have not deemed it necessary, while experimenting, to supply data relating to a more advanced period of the disease, since it was incumbent upon us to demonstrate the possibility of curing, safely and with moderate doses of serum, an attack of rabies at the beginning of the period of incubation. This disease presents, in contrast with other maladies, the peculiarity of following a course in which is marked out with precision the moment of contagion and the development after a long period of incubation. Hence it is possible to apply the treatment soon after contagion without expecting that the disease will be more severe on the appearance of the first morbid manifestations. We have not occupied ourselves with any other aspect of developed rabies in the preceding researches; they are only approximately of value for actual calculations, since we are not yet in possession of exact methods of administration. The serum had a power inferior to that actually calculated, and we injected the mean dose of 1 in 100 for the intra-nervous infection with canine virus on the appearance of decrease of weight and of the first signs

of paresis. From this we can argue that at the period stated successes can only be obtained with quantities of serum about 100 times greater than the protective dose. The curative experiments made upon animals by means of subdural infections, though less numerous, confirm those made with intra-nervous infection, and give an idea of the limits between which the facts vary in passing from one mode of infection to the other. We see, in fact, as on the second day of infection, that there is not any noteworthy difference, since a dose of 1 in 4000 is required where the infection is in the sciatic nerve (Example 85), whilst for the subdural infection one of 1 in 2800 is necessary, nor do we know whether that is the maximum. On the fourth day a noteworthy difference is noticeable, since a dose of 1 in 2000 (Example 136) is no longer sufficient, while for infection in the sciatic nerve this dose is of service, as also is a lower one, as we find a dose of 1 in 3000 still active on the eighth day. We ought, therefore, to admit that in the cerebral infection there is a more rapid multiplication of the virus, which agrees with what has been established as to the manner of propagation of the virus of rabies in the organism. And with regard to the treatment we are able to say that when begun immediately after infection an almost equal dose of serum suffices, whatever may have been the part of the nervous system in which the virus has been deposited; but for ever so little later the dose of the serum should always be increased the nearer the seat of the rabid inoculation is to the nerve centres.

Course of the malady in the cured animals.—The weight of the infected animal continues normally to increase up to beyond half of the period of incubation, when the decline commences, which becomes rapid towards the close. However, there are cases in which the decline of weight commences much sooner—i.e., a little after the infection—and proceeds without interruption up to the death of the animal. In the cured animals the beneficent effect of the serum does not fail to show itself by arresting this fall whenever it may begin. The customary result is not perceived at the moment, but soon afterwards the lowering is prolonged for one, or at most two days. After that the curve again rapidly ascends. We give two very instructive examples of the former and the latter behaviour of the weight: they are taken from two experiments given in Table XV. In Example 146 the line representing the weight is found still in the ascent, till the moment of the injection of the serum (tenth day), but soon, during the progress of the infection, a decline commences, which after two days is checked by the action of the antitoxin. Still more evident is the influence of the serum in Example 147. The line representing the weight at the moment of the injection of the serum (eighth day) was found to be constantly declining, but after having continued for one day it is suddenly interrupted in order to give place to a rapid rise. When the treatment is undertaken promptly, and when there has not yet appeared any evidence of rabies, the animal as a rule manifests no sign of the infection and continues to comport itself as a perfectly healthy animal. On some rare occasions, however, an interesting fact presents itself. During the period corresponding to the regular development of rabies loss of weight commences, as well as a stupidity which from the first makes us fear the loss of the animal. This period surmounted, the animal, without any other treatment, picks up again towards the twentieth to the twenty-fifth day, and continues to keep healthy. There are (residual?) forms of rabies analogous to those which are found in persons who have undergone Pasteur's treatment and to which Murri and Bordoni Uffreduzzi have recently called attention.

VI.—ON THE NEUTRALISING POWER IN VITRO OF THE ANTIRABIC SERUM.

That with a small quantity of serum we should be able to neutralise, by simple contact outside the organism, the action of comparatively large quantities of the canine or the fixed virus was a fact already established by our earlier researches and only needed an exact determination of the limits of time and of quantity within which we were able to obtain this special action of the serum; our observations had not enabled us to assume for them the scientific and practical value which we now know, as a result of our renewed researches, undoubtedly appertains to them. Over and above its scientific value we have attached importance to this fact in order to discover by means of it a method of determining the strength of the serum which would be most advantageous. The method of determining *in vitro* is, in fact, the most exact scientifically, and the most convenient practically. Scientifically, it gives the absolute quantity of the virus which the serum is capable of neutralising, since in the method *in vitro*, as Behring and Ehrlich have noted, the varying conditions of individual sensibility do not come into play, nor do those of absorption and elimination from the body of the material injected. The advantages in the determination of the power of the serum from a practical point of view are most remarkable. Above all, there is a saving of time, the operation being performed there and then without an interval of twenty-four hours between the injection of the serum and that of the virus. Particularly when the mixture is made by multiples we can as early as the fifth day argue from the weight of the animal what will be the issue of the experiment; on the eighth day an absolutely safe conclusion may be arrived at, because in the determination by multiples, on introducing a strong quantity of virus, if in the mixture there remains undecomposed even merely a trace for each unit, this, repeating itself for as many multiples as there are, becomes capable of rapidly causing death. Thus it becomes superfluous to subject the animals to examination for any length of time. The determination by multiples of the infecting unit presents also the advantage of diminishing some of the uncertainty in the results, provided large quantities of the virus have been introduced; on the other hand, all the causes of uncertainty which we met with when making use of a minimum of infection come to be lessened by reciprocal compensation in the case of multiples. A not insignificant advantage is the economy in the matter of serum, since, in operating with the fixed virus, twenty-six c.cm. of serum per cutem is needed for every animal, whereas by the determination *in vitro* small fractions of a c.cm. are sufficient. Henceforward, in the determination of the serum the method of direct mixture may now be almost exclusively adopted, using fixed virus and injecting the mixture under the cerebral dura mater. As the basis of our calculation we take the number of the infecting units which a c.cm. of serum is capable of neutralising. Practically, the mixture cannot be prepared by making an emulsion there and then of a small quantity of virus in the serum, because the smallest portion of this virus contains a great number of infecting units and would consequently demand a considerable quantity of serum. Instead, we mix the serum

Digitized by Google

at a given dilution with the water of the virus itself. In the first experiments we used to mix a part of the serum with 10, 20, or 30 parts of emulsion of fixed virus, which represented 1 c.cm. of serum mixed with 800, 1600, or 2400 infecting units. In order to inject with the mixture an infecting unit of the virus it was necessary to very slightly increase the usual dose of emulsion employed, since the serum represented a very small proportion of the total volume. But in order to conduct the experiment with multiples—that is, to introduce such a quantity of the mixture as will contain more infecting units—one cannot sufficiently dilute the virus so as not to unduly increase the volume of the liquid by introducing it under the dura mater. We have, therefore, used the dilution of 1 in 50 to 200, regulating the quantity of the serum in accordance with this increase by mixing. In the last experiments with our typical serum made with the fixed virus, the unit of dilution of which is 1 in 5000, we have thought fit to make use of the dilution 1 in 1000 (five infecting units) mixed with serum ordinarily in the relation of 1 to 1, 1 to ½, 1 to ¼, and 1 to ⅛, which corresponds with 1 c.cm. of serum in contact with 400, 800, 1600, and 3200 infecting units; and by regularly injecting, along with the mixture, five infecting units we hope to combine with facility of preparation, on account of its simplicity, greater safety in the results, the multiple of least infection being employed. As to the period of contact, we, on principle, adopted a period of twenty-four hours at the temperature of the atmosphere; then, having ascertained that the action of the serum was independent of the time of contact—just as in the case of other infections—we injected the mixture a few minutes (five to ten) after it had been made. Before entering into this line of research we wished to ascertain whether our results might in any way be referred to an influence which the normal serum itself would exercise upon the virus of rabies. The experiments made on the serum of sheep, normal as to the identical conditions of dose and time observed in the case of the antirabic serum, have shown that of the animals thus treated one and all died.

In Table XVI. we report a series of trials *in vitro* of some samples of our normal serum. The experiments were practised with the serum of four groups of sheep, vaccinated and strengthened according to the plan described at the beginning of this article. The third column of the table indicates the proportion between the serum and the virus with which the mixture *in vitro* was made. In the fourth column, on the other hand, the portion of this mixture is given—that is, the neutralised infecting units which the animal received during the relative experiments. In all the four groups we note a uniformity of results, although the vaccinations were made at various times, and we treat of fresh sheep (Group 3); of sheep strengthened for the first time, giving the dose (Group 2); strengthened for the second time (Group 4); and strengthened for the third time (Group 1). These experiments, too, serve to confirm much of what is said in Part IV. of this article with regard to the question of the rise of the power of the blood under repeated vaccinations. In all the four serums it is seen that the neutralising power always oscillates between the same limits of 1 to 800 and 1 to 1600 (mean 1 to 1200)—that is, a c.cm. of serum is capable of destroying the action of 1200 infecting units, so that for our typical serum the protecting unit comes to correspond in the mean to 0·00083 c.cm. of serum. That is equivalent to saying that a c.cm. of our typical serum is able to preserve 1200 rabbits weighing one kilogramme each from infection by the fixed virus—a power which, referred to the body weight, as is done in the case of separate injection of virus and serum, attains to the figure of 1 to 1,200,000. The power very nearly approaches 1 to 1600, since in eight experiments (Nos. 169, 209, 238, 239, 265, 270, 271, and 284) death ensued only in two (Nos. 238 and 271), and in these not until the tenth and sixteenth days respectively. Above 1 to 1600 the positive results do not definitely cease, but continue gradually to diminish until in three experiments made with a strength of 1 to 2400 (Nos. 170, 210, and 266) we had only a single success. There are small oscillations due to differences in individual sensitiveness and in the graduation of the infection, as already many times mentioned. The table likewise furnishes us with information regarding the multiples. Although our experiments in this direction, especially in the case of the higher multiples, are not very numerous (we may possibly return to the subject), yet they elucidate as much as Behring and Ehrlich admit for tetanus and diphtheria—that is, that when the mixture of serum and virus is properly neutralised a considerable dose can be injected into the animal with impunity. We find that the relation of from 1 to 800 to 1 to 1600 is maintained when we inject five neutralised infecting units (Group 4). Example 189, for instance, shows that of the mixture 1 to 800 we can inject with impunity fifty fatal doses of virus; lastly, the experiments of Group 3, made with the infection of 100 neutralised infecting units, demonstrate that for the power of 1 to 1600 the result is uncertain (one favourable and one unfavourable)—results differing in no wise from those obtained when a single infecting unit or one of the lowest neutralised multiples of the same mixture is injected.

VII.—THE DIRECT PROTECTION OF THE NERVOUS SYSTEM.

In comparing the dose of the serum required to neutralise a determined quantity of fixed virus when the serum is injected under the skin with what occurs when the direct method is used we have been struck with the great difference observed in the two cases. By the direct method of contact *in vitro* the power of the serum appears to be immensely greater; the infecting unit of the fixed virus being taken as a base, we have seen that in order to neutralise it 10 c.cm. of our typical serum is required for the subcutaneous method, against only 0·00083 c.cm. for that by direct contact, and that the subcutaneous dose represents 12,000 times the dose where the direct contact method is used. We have asked ourselves, What can be the reason of this enormous difference, and by what means does the serum act in the two cases?—a question which has also been raised in the case of other infections and which has not been satisfactorily settled. Starting from certain considerations based upon the elective seat of action of the rabid virus, and guided by indications collected with regard to the localisation of immunity in this infection, we have been induced to inquire anew whether by injecting the serum directly into the nervous system, or under the skin, we could obtain by means of the same minimum doses as those employed when mixed with the virus the same effects as when this mixture was used. We have divided the experiments into four categories. In the first we have injected separately under the cerebral dura mater an infecting unit of virus and a protective unit of serum. In the second category, after a single infecting unit has been injected, we have injected further units of serum. In the third we have employed multiples—as many for the serum as for the virus. All the experiments of these first three categories have been made by injecting serum and virus separately after a lapse of time, but making use of the same trephine opening. In the fourth series, on the other hand, the serum and the virus were injected simultaneously, the one being introduced at a point of the nervous system far from that in which the injection of the other had been effected. For the injections of the virus we employed the path of the brain and of the sciatic nerve; the serum, on the other hand, has always been introduced under the cerebral dura mater. A rabbit of a mean weight of one kilogramme and a half supports the subdural infection of 0·5 c.cm. and also 1 c.cm. of serum at the same time without any morbid symptoms, and, if the operation is performed with care, without danger of reflux. The following table gives the relative results of these experiments. (See Table XVI.) The fact which indubitably results from the completion of these experiments is that antirabic serum injected directly into the central nervous system, separated from the virus, is capable of acting as effectually, in average dose, as when the mixture is made *in vitro*. We see, in fact, a single protective unit succeed—that is, 0·00083 c.cm. of serum (Examples 179 and 180); also the higher doses are employed against a multiple of infecting units; they have never been higher than those of 0·30040 c.cm., which are very far from as many as are required by the subcutaneous method against a single infecting unit or against a multiple. This fact induces us to believe that of the large quantity of serum injected under the skin only an imperceptible part may be utilised—viz., that which succeeds in coming into contact with the part sensible to the virus—in our case, the nervous system. The large residue must be lost not only because it is diffused in the whole organism, whilst the protective action must extend only over a small part of it, but also because a quantity is destroyed within the body and is eliminated by the organs of secretion. The serum injected under the skin diffuses itself in the entire organism

Digitized by Google

by means of the circulation of the blood in the lymphatics, whilst when it is injected under the dura mater it comes into direct contact with all the elementary parts of the nervous system by the special lymphatic paths which we know to be directly in relation with the nervous elements and which act independently of the general circulation. This is an established fact. It remains to be seen whether this series of experiments can elucidate what is demanded from protective serum. Let us make a more minute examination of the table. The first three categories of experiments—A, B, C—are made by introducing the virus into the neck at the same spot at which the serum was introduced some time before. This fact would lead us to surmise that here also one has to deal with a direct action of contact such as takes place *in vitro*, inasmuch as the twenty-four hours allowed to pass between the injection of the serum and that of the virus (Examples 107, 176, 191)—and, much better, the three days (Example 180)—would allow sufficient to be retained, because the serum is diffused and enters into the circulation by means of the cerebro-spinal fluid. But here the experiments of category D, which are made by introducing the serum and virus at the opposite extremes of the nervous system—the virus in the sciatic nerve and the serum in the brain come to our aid. These experiments are very conclusive, and it must be admitted also very elegant. We have drawn special attention to them, as the whole series, except the experiment made with the minimum of serum (Example 288), were entirely successful, although the *animals* infected in the sciatic nerve with the fixed virus—numerically equal to the animals cured—all succumbed to rabies. Notwithstanding these results the objection of a direct action is not completely overcome, since the serum injected even into the furthest points can be conveyed by means of the lymphatic circulation into direct contact with the virus deposited at the point of infection. But if the serum deposited in the brain penetrate along the sciatic nerve the cerebro-spinal fluid must be diffused to all the nerves, central and peripheral. And in this case the smallest quantities of serum introduced ought to undergo such a dilution by coming into contact with the virus, which is in proportion infinitely less, as the contact experiments *in vitro* have demonstrated to be necessary for a complete neutralisation. Nor does it avail to object, as appears from the fourth column of the table, that when the serum and the virus are injected separately a single protective unit does not suffice to neutralise an infecting unit, but that it is necessary to introduce a multiple dose to at all compensate for the greater dilution which the serum must undergo before coming into contact at the infective centre. It results, in fact, from category A that a single protective unit suffices in two or three cases, and if in the categories B and D a multiple of the serum has been introduced this is always too weak to be able to act after so extended a diffusion, independently of the fact that perhaps those doses can be reduced still more considerably. We are, therefore, continuing to work at a fresh series of experiments made upon rabbits and dogs with the object of determining what is the least dose of serum introduced into the brain necessary to arrest the infection made in the sciatic nerve and in the eye, and we hope at the same time to establish the period after infection, and the dose of serum, at, and with, which it may be possible by this kind of treatment to cut short the course of the rabic attack. Meanwhile, however, the experiments which we have made up to the present give rise to the suspicion that the phenomena of neutralization *in vitro* of the virus by means of the serum may be only apparent, and that, on the other hand, the serum introduced with the mixture, acts on its own account on the part specifically sensible to the given virus, so hindering its cultivation. Consequently, the dose of the serum which in the mixture is held to be necessary to destroy the given quantity of the virus would not be able to sufficiently guard the sensitive tissues of the body against the quantity of the virus introduced with this mixture. Certainly the objection which a similar interpretation has met with in the analogous experiments for tetanus and diphtheria—that is, the great difference of the dose in which it acts in the body, and *in vitro*—cannot, in the light of our experiments, be raised in the case of rabies. We do not wish it to be believed that we insist on this argument for the sake of a theory; on the contrary, we are convinced that this point of view, besides illustrating more completely the conception of the new therapeutics by means of protective substances, opens up new paths of research and new applications to practice. To the general conception of specific immunity will have to be added in future that of elective immunity, general specific therapeutics will have to give place, wherever possible, to specific local therapeutics, the serums being introduced directly into those parts which are most favourable for their protective action against the invasion of the morbific agent. From this system of treatment two great advantages may be derived—viz., rapidity of action and the exhibition of small quantites of the remedy. In certain cases, when great quantities of virus are present the doses of serum required to neutralise it when introduced under the skin, would be so great that cure by this way is evidently impossible. In fact (Example 191), we have been able to save one animal by means of only 0·16 c.cm. of serum introduced into the brain, while if we had used 50 infecting units by the subcutaneous way we should not have been able to succeed with less than 500 cubic centimetres. The practical outcome is that in developed rabies, for which a large multiple of the least mortal dose has been given, the medulla must be protected against the progress of the disease, and for this purpose one cannot hesitate to have recourse to the

TABLE XVI.

expedient of introducing serum directly under the dura mater by means of trephining.

VIII.—APPLICATION OF ANTIRABIC SERUM-THERAPY TO MAN.

The final aim of our researches on rabies scarcely needs repetition—it is that of substituting for Pasteur's vaccination method, in the case of a patient who has been bitten, the treatment with protective serum. In our preceding works we have been somewhat reserved on this point, wishing, on principle, to restrict the application of the serum to the more grave cases outside the range of an antirabic institute, we have done this simply from excess of prudence and out of respect for a method of cure of tried efficacy. But now, after our recent experimental results, which confirm, complete, and clear up in the most minute particulars earlier experiments, and after having taken a stronger serum and found a more exact method of determining its activity, there is no reason for such reserve, and we have no longer any doubt that the treatment by serum in rabies must be soon and completely substituted for Pasteurian vaccination.

1. *Experimental superiority of serum treatment over the vaccination of Pasteur.*—By means of a course of study continued in this laboratory without interruption for six years we have endeavoured to rest the serum treatment of rabies upon a larger and firmer experimental basis, convinced that the experiments of the laboratory would at last find their complete application in the practical field—as already we find those upon serum treatment in tetanus and diphtheria and those of the antirabic vaccination of Pasteur. Now if we compare our experiments and those which justify Pasteur to come to their application to man, we feel we are decidedly in a much stronger position—we are able easily to protect the rabbit, an animal excessively susceptible to rabies, and which we know can only be exceptionally protected by the vaccination method of Pasteur; we are able with a single injection, made twenty-four hours before the subdural infection, to preserve the rabbit from the virus of rabies "da strada," whilst we know that by Pasteur's method it is necesary to make many injections and to allow many days to pass from the beginning of the vaccination before the animal is able to bear the subdural infection. We are able to save the rabbit by a single subcutaneous injection—also after the subdural infection and in an advanced stage of the period of incubation—whilst by Pasteur's method one never succeeds under these conditions in saving the animal. We succeed with a single subcutaneous injection, made a little before trephining, in preserving the animal from subdural infection with virus of the greatest strength—with the fixed virus—which the Pasteur method never succeeds in doing. Now, if the applications of the Pasteur method which have been made upon man are only the logical consequences of experimental facts, it is natural that the same justification for application to man—and even greater justification—should be found in that method in which the experiments are very much more conclusive. Only in the presence of the Pasteur method we felt that we could ourselves make a grave objection, and that was regarding the duration of the immunity, which for the treatment with serum we know in general to be much less than the immunity determined by vaccination. However, such a question loses its importance from the practical point of view when it has been established that the action of the serum in the organism is that of neutralising the action of the virus, and that, taking care to introduce the dose of serum sufficient to exert this action, we prevent for ever the development of the disease.

2. *Practical advantages of serum treatment over the vaccination of Pasteur.*—Rabies is one of the few infections in which this question is of practical interest, because, given the special conditions of contagion and incubation, it becomes possible in it to apply a treatment of vaccination after the infection has taken place; on the other hand, in the greater number of infections in which one can only intervene in a case of developed malady this discussion would be out of place, because vaccination in such conditions, if it does not aggravate, is not the least help to it in any way. It is very true we have tried in developed rabies to have recourse to vaccination, trying to find a way in which the material can be caused to be rapidly absorbed. We would speak of the method of Murri, by means of injection of the emulsion of rabies into the veins. But the few experiments of this writer were made exclusively on persons placed previously under the care of Pasteur, and, as we have already said, demonstrate little as to healing taking place in similar conditions without treatment of any kind. Whilst, then, the trials made on man and animals not placed under any previous treatment without exception ended in failure, we are able to divide the advantages of serum-treatment over the vaccination of Pasteur into two categories—the first greater efficacy, the second greater convenience. The greater efficacy of the serum in comparison with vaccine arises, above all, out of the property of the serum of acting rapidly, since it, as the final product of the vaccination from which it proceeds, has no need of a long period of preparation within the patient. The utility of immediate action follows clearly, from what we have previously demonstrated, as to the strict proportion which exists between the quantity of the virus and that of the serum necessary to destroy its action. We must imagine that generally with the bite of a rabid animal there is introduced into the body, by means of the saliva, only a very small quantity of the virus, a quantity so trifling that in considering the small number of persons bitten by a rabid animal who contract the disease it must approach almost always to the least mortal dose. Now, knowing that during the period of incubation, and before there is any manifestation, a certain multiplication of the virus introduced takes place, it will be understood how the cure can be rapidly effected and how favourable results must be obtained. When we inject the serum under the skin the blood, within a few minutes, acquires a protective property. In vaccination, on the contrary, this formation of the protective product takes place very slowly, so that in our vaccination experiments—pushed on rapidly—of rabbits we were not able to make the trial infection until at least fifteen days from the beginning of the vaccination. This slowness of action is recognised in the method of Pasteur—in fact, with this method the result is not guaranteed, and in the statistics the deaths are not taken into consideration before fifteen days have passed after the treatment is exhausted, so that, calculating twenty to thirty days as the mean duration of the vaccination, we have to wait for a period of thirty-five to forty-five days before the cure can be declared efficacious. We have analysed, in the "Annals of the Pasteur Institute," the cases of death taking place in the Institute during and after treatment, and we have found that the greatest number were cases with a short incubation period (twenty to thirty days), which shows how in these conditions the Pasteur cure succeeds in being of little efficacy. Serum treatment ought also to have over vaccination a superiority with which the latter cannot compete when the cure has only been undertaken at an advanced period of the incubation, or when we are treating a deep bite made in the course of large nervous trunks and in the neighbourhood of the brain. In Russia, where serious wolf-bites are frequent, the mortality of the cured, notwithstanding the most intensive method, remains always considerable. Then, too, the advantages as regards convenience which our preparation has over the inoculation of Pasteur are not at all to be despised, because they, according to the last analysis, not only enhance the efficiency of the method, but allow of a rapid and general application. Our remedy consists of a solid material, preservable, not dangerous to handle, which can therefore be sent anywhere and can be applied by all medical men, just as can any other remedy, by subcutaneous injection. It is not needful to remember how, on the contrary, for the Pasteur vaccine special institutes are necessary, where the material is prepared day by day, and where the patient has to be taken directly, involving pecuniary considerations and the loss of most precious time. The complete absence of any virulent action whatever in our preparation not only assists its employment in practice by less expert hands, but overcomes the reluctance which many feel to having themselves injected under the skin with a great and increasing quantity of fixed virus, although the fear may be unfounded, the vaccination of Pasteur being discovered to be quite harmless. Our preparation gives the least local irritation, and by being easily soluble and assimilated the local symptoms of Pasteur's numerous and abundant injections are minimised—symptoms which, if not serious, are certainly very disagreeable. We do not wish to place the economic advantage in the last category. The charge for the Institute (60 and 100 lire per head), the maintenance for twenty to thirty days, the expenses of the journey, and the interruption of business constitute either an expense that the individual can ill afford or a burden on the community. The treatment by Pasteur's method, notwithstanding its indisputable efficacy, tends to

Digitized by Google

become unpopular precisely according to the degree of these inconveniences. We have a clear proof here in Italy that, though institutes against rabies are established everywhere, there still appear in the bulletins of public health from seven to fourteen deaths from rabies a month—about 100, that is, per annum.

3. *Criteria for the dose and for the manner of application in man.*—The recent publications on serum treatment demonstrate how these data are completely established by experiments on animals. As to rabies, from this point of view we find ourselves in a more advantageous position, since the method of Pasteur already established constitutes for our method a good standard of comparison in man. For the application of the antirabic serum treatment in man we ought to start from the established fact that a given quantity of serum neutralises a given quantity of virus, and, making use of the experimental data, we should establish some proportional relations between the dose of the serum held to be efficacious in the rabbit and that which would serve for man. The first datum which is necessary for this determination is to know the quantity of virus which is found in man at the moment at which the treatment is applied. To judge by the small proportion of persons who, bitten by rabid dogs, are attacked by rabies and by the weak concentration in which the virus is found in the saliva, we must hold that the quantity of the virus deposited in the wound with the bite of the rabid animal approaches nearly always to the minimal lethal dose. And since rabies can be cured at the first moment of the period of incubation, and we know by our experiments that during the first half of this period a considerable multiplication of the virus does not take place, we should find ourselves at the moment of the application of the remedy in the presence of small quantities of the virus, which must vary between very narrow limits. On the other hand, in the infections in which treatment of the declared malady is only possible, as in tetanus and diphtheria, by reason of the conditions in which the infection and the multiplication of the virus take place, there must be some very marked differences in the quantity of the pathogenic principle to be neutralised by the serum. That for single cases must render necessary enormous doses of serum and reduce to much uncertainty the issue of the treatment. We will add here also that in rabies those objections cannot be raised with regard to serum treatment which justly are an obstacle in mixed infections, such as diphtheria, preventing a complete success of the treatment. The dose of the virus with which the infection is given in man can be compared with advantage to that introduced into the rabbit by the subdural and nervous infection, and the comparison results so much more favourably for man, inasmuch as he is not so susceptible to rabies as is the rabbit, nor is the virus deposited directly at the point of greatest sensibility, as in the nerve centres and the great trunks. And that in the rabbit, precisely in regard to this point, the question of protection may be more difficult, is demonstrated by repeated experiments made on applying to it the same series of vaccinations according to Pasteur which are made in man. Although the treatment may have been preventive, and followed by a long latent period before infection, yet such animals infected by the subdural method by the canine virus are saved in a very small proportion of cases. The experiments upon the rabbit relative to the dose of the serum (restricting ourselves always to the results comprised within the limits of absolute certainty) tell us that, as we have seen, for the canine virus the dose of our typical serum is of the strength of 1 in 25,000—that is, 0·04 c.cm. per kilogramme of the weight of the animal; but, passing to the curative dose against the virus, we have found that up to the fourth day after the infection it rose to 1 in 4000—that is, six times the preventive dose, corresponding to 0·30 c.cm. of typical serum per kilogramme. Applying this calculation to man, we find ourselves, let us repeat, in more favourable conditions; and, calculating upon a mean weight of the body of 70 kilogrammes, we find that the curative dose, after a sudden bite has taken place, corresponds to 20 c.cm. of our typical serum, being equal to from 2 to 5 grammes of the dried product. Now, wishing to render ourselves independent of variations of the activity of the serum, we shall adopt a standard of measurement—similar to that used in the case of diphtheria—viz., a protective unit; and we assert that in order to treat rabies a little while after the bite 25,000 protective units are necessary—that is to say, the dose of serum sufficient to neutralise the quantity of fixed virus capable of killing 25.000 units of the weight of one kilogramme. As to the manner of injecting the dose instead of introducing it all at one time, as we have done in animals, we think it may be more convenient to divide it, in the belief that the too sudden accumulation of a foreign material in the blood may favour elimination and hence the loss of active material. We advise, therefore, the division of the strongest dose into three injections—the first to be made at once, injecting half of the dose above determined, and the rest divided into two equal doses at intervals of three days, so that the whole treatment is completed in the course of a week. We should always keep before us the fact that the dose is relative to the period at which one begins the cure and to the power of the infection; therefore, the dose given is of value, as regards a bite of mean gravity, for treatment undertaken during the first four days after the infection, and we hold that, with the practical facilities which serum treatment offers in rabies, such a period of time ought never to be exceeded. From the fourth to the fifteenth day after the bite we advise that the dose of serum should be doubled, the same order in making the injection being still followed. We hold that this doubling of the dose is essential. We also hold that the dose should be a bold one in the case of more extensive and deeper bites, or such as are made in proximity to the nervous centres, especially those on the face.

Clinical Notes:

MEDICAL, SURGICAL, OBSTETRICAL, AND THERAPEUTICAL.

UNRUPTURED HYMEN AT FULL TERM OF PREGNANCY.

BY EDWIN T. ENSOR, M.D. NEW YORK.

THE following case, although not by any means unique, is, I think, sufficiently rare to make it worthy of record. All have heard and read of such, but in an experience of something like 4000 labours, extending over a good many years, I have never personally met with such a one before.

The patient was a woman about forty-two years of age who had been married ten months. Her husband, unmarried previously, was a very corpulent man, apparently of the age of forty-five. On examination I discovered the existence of a perfect hymen, which admitted the passage of the index-finger without difficulty, but not of the first and second fingers without risk of rupture. The presentation was normal, the head being in the first position: the membranes were intact. The labour was very slow. When the dilatation of the os was practically complete I ruptured the membranes, and twelve hours later delivered under chloroform, administered by my friend Dr. Bawden. The hymen was ruptured in the application of the forceps, but there was no perineal laceration, and the child, a well-developed female, was living. The total duration of the labour was forty-five hours. Both mother and infant are doing well.

Chesterton-road, W.

A CASE OF TREPHINING FOR INJURY TO THE HEAD PERFORMED AT SEA.

BY J. TERTIUS CLARKE, L.R.C.P. LOND., M.R.C.S. ENG.,
SURGEON TO THE BRITISH INDIA STEAM NAVIGATION COMPANY;
LATE HOUSE SURGEON, ROYAL HANTS COUNTY HOSPITAL, WINCHESTER.

AS I have a very clear recollection of two cases of compound depressed fracture in which, I think, trephining was imperatively called for, but not done, both of the patients dying, and as in the following case the operation was performed under somewhat disadvantageous circumstances I hope that it may be of use to publish it. At 11.30 P.M. on June 24th, 1895, I was called to see an ag-wala, or native fireman, on whose head an iron ash-bucket, weighing about 25 lb., had just fallen from a height of about 20 ft. The man had not lost consciousness but had a curved scalp wound about three inches long, at the bottom of which was

Digitized by Google

a depression in the bone about two inches long, with a fissure at each end extending beyond the angles of the wound. The length of the depression passed outwards and forwards, the inner end lying just to the right of the middle line and in front of the coronal suture, the anterior edge being depressed below the posterior. There were no spasms of any kind or symptoms of pressure, but I decided to elevate or remove the depressed fragment as soon as I could get things ready. Fortunately, an Indian medical man, Dr. Mittra, was on board, who kindly assisted me by giving chloroform. The wound was enlarged by half an inch in both directions laterally; and an incision an inch and a half long was made, passing forwards from the middle of the anterior edge so that two triangular flaps could be reflected and more room obtained. The bleeding was stopped, and a three-quarter inch trephine applied to the bone in front of the depressed portion; a disc was removed, and as I found that the bone was so tightly wedged that it could not be raised the trephine was reapplied, and a segment as large as three-fourths of the trephine area taken away. I then removed the remainder of the depressed portion with forceps and elevator. The dura mater I found to be intact. The oozing was stopped by hot-water not sterilised, the wound was dried and the flaps sutured, a small piece of tubing being left in; the dressing was iodoform, lint, and wool. I left no fragments of bone lying on the dura mater, as I was not at all sure—in fact, I was very anxious—about my antiseptics, a ship not being the best place for an operation. This had been performed on one of the hatches, my assistants being, of course, untrained; dirt was plentiful, the lights were indifferent oil lamps, the patient's head was less than two feet above the ledge on which I was standing, and the ship was rolling all the time. The man was left on the hatch on which the operation was done until the next morning, when he was removed to a cabin. He bore the operation well, although it took a considerable time chiefly on account of the conditions under which it was performed. His highest temperature was 100·4° F. at 11·30 A.M. of the next day, afterwards it did not rise above normal; his pulse was very slow, usually not over 50, and there was slight pain in the head. He slept well and took food well. On the 29th he was moved into Colombo Hospital in order to avoid a long voyage, and about a week or ten days after was sent up to Bombay by boat. The wound did not suppurate at all.

Colombo.

THE EFFECT OF THYROID EXTRACT IN MYXŒDEMA COMPLICATED BY ANGINA PECTORIS.

By H. C. L. MORRIS, M.D. BRUX.

A MAN aged forty-eight came under my care some months ago, having suffered from myxœdema and occasional attacks of angina pectoris for several years. The patient not having received any appreciable benefit from treatment, I determined to try thyroid extract, watching carefully the effect upon the heart. I began with half a tabloid (5 gr.) twice a day. On the fourth day he was seized with two most severe attacks of angina, lasting over an hour, and gave me much anxiety. I at once stopped the extract, but at the end of a few weeks, at his request, I made another trial, giving him the unusually small dose of 2½ gr. every second day. He experienced no discomfort until the twelfth day, when he again had a severe attack of angina pectoris, and I had again to discontinue the extract. Neither before nor since have his attacks been anything like so serious. The pathology of the case is puzzling, as Schäfer has recently pointed out that thyroid extract distinctly lowers the blood pressure. Perhaps the angina was produced by its action on the central nervous system.

Bognor.

A CASE OF CARBOLIC ACID POISONING; RECOVERY.

By RICHARD CATON, M.D. EDIN., F.R.C.P. LOND.,
PHYSICIAN, LIVERPOOL ROYAL INFIRMARY.

THE patient, a young woman aged seventeen years, was brought to the Liverpool Royal Infirmary at 1.22 P.M. on March 2nd, 1895. On admission she was comatose, with stertorous breathing, the breath smelling strongly of carbolic acid. Her conjunctival reflex was absent. The skin was dry and the tongue dry and brown, with fungiform and filiform papillæ very prominent. The pulse was thready and too frequent to count. On examination of her fauces a few greyish-white patches were to be seen, and one especially large white patch on the soft palate. There was considerable swelling of the faucial tissues. The pharynx would not admit of the introduction of the tip of the little finger. On removing the little finger after examination of the fauces it was found to be covered with blood. A hypodermic injection of twenty minims of brandy was given, and several attempts were made to pass a small, soft stomach tube, all of which were unsuccessful owing to the swelling of the faucial tissues above described. A hypodermic injection of one-tenth of a grain of apomorphine was then given. In twelve minutes the patient vomited a little undigested food, a trace of blood being present with it. The vomited matter smelt strongly of carbolic acid. She was then removed to the Clarence Ward and placed in a bed already prepared for her, with hot bottles, and a steam tent was fixed up around the bed. Hot fomentations were applied to her neck; on the application of these her pupils dilated widely. Three quarters of an hour after her admission she showed signs of returning consciousness. She now became very cyanosed and rather more collapsed, so I tried to stimulate her respiratory, cardiac, and vomiting centres by one-fiftieth of a grain of strychnine, given hypodermically. After the administration of this the cyanosis gradually disappeared and her respiration became more natural. During the whole of this time her tongue was held forward, as was also her jaw, and the fauces were repeatedly cleared of mucus. About three quarters of an hour after the hypodermic injection of strychnine she vomited several times. The vomited matter consisted of undigested food, mucus, and several small blood clots; it smelt strongly of carbolic acid. She now recovered consciousness and had small quantities of milk (one drachm at a time) by the mouth, which was swallowed with difficulty. In the evening she was put on a mixture containing carbonate of bismuth, bicarbonate of soda, carbonate of magnesia, and water. The pupils became normal. The respiration was 25 and regular in time and force. On March 3rd the respiration was 30 and the pulse 120. There was a blister filled with serum on the left thumb. The urine was almost black and of sp. gr. 1022; the reaction was very acid and it smelt strongly of phenol; it contained no albumin. With bromine water it gave a yellow precipitate; with perchloride of iron added drop by drop a violet colour was produced. On March 4th there was great tenderness on pressing over the region of the tonsil. The temperature was 100·2°F. There was great difficulty in swallowing, and carboluria still existed. For the first time albumin appeared in the urine. The respiration was 20 and the pulse 100. On the 6th there was still carboluria. There were a few moist sounds in the chest, with bronchitic expectoration. On the 7th the pulse was 80 and the respiration 20. There was no trace of carbolic acid and no albumin. The patient continued to improve and had her diet gradually increased from fish and chicken to an ordinary diet. The bowels were kept regular by enemata of one ounce of glycerine till March 16th, when she had half an ounce of castor oil when required. The patient left the infirmary on March 25th perfectly well. This case was reported by Dr. S. J. Ross, house physician, and was treated by him during the acute stage.

Liverpool.

A CASE OF BELLADONNA POISONING.

By W. T. MOULD, L.R.C.P. LOND., M.R.C.S. ENG.,
SURGEON-CAPTAIN, ARMY MEDICAL SERVICE.

ABOUT 2.45 P.M. on Aug. 4th, 1895, I was called to see an officer at his bungalow. I found him lying on his back and deeply comatose; the breathing was stertorous and the pulse full and bounding. There was spasmodic twitching of all the limbs and face, this being much more marked on the left than on the right side. The plantar reflex was exaggerated, but I could not elicit the knee-jerks, nor was there ankle-clonus. The pupils were widely dilated. The history was not very clear; his native servant had called in a brother officer to see him, as he said he was making "a noise and was convulsed." This officer then sent for me. On questioning the servant I found that about 1.30 P.M. he had taken a dose of medicine—I was at the time treating

Digitized by Google

him for some diarrhœa of a dysenteric character. This medicine was a ten-grain Dover's powder, and the bearer had mixed it with belladonna liniment instead of water. The liniment had been ordered that morning for a contused shoulder and had not been used. I at once took the bottle with me and went to the hospital, on my way calling on Surgeon-Captain Healey for assistance, and as he had some hypodermic solution of morphia he at once went and injected a third of a grain. I found that nine or ten drachms of the liniment ordered that morning were missing. On returning with the stomach pump I found the patient in the same condition, but he struggled violently during the passage of the tube. About a pint of warm water was introduced and withdrawn from the stomach. The patient's struggles still continued and he retched violently so that the tube had to be taken out, when he vomited. After a short interval the tube was again passed, and as the struggling and retching were less the stomach was washed until it was quite clean. The first washings were brown and smelt strongly of the liniment, but later were quite clear and free from smell; they contained but little food as he had only had some toast and milk with limewater that day. At 6 P.M. another third of a grain of morphia was injected. The symptoms still persisted except that breathing was less stertorous and the twitchings had completely passed off. Between 8 and 9 P.M. he gradually roused and became noisy, and tried to get up to go to the bathroom to micturate, but on being given the utensil he was unable to relieve himself. From this time he was noisy and delirious, and at half-past nine I gave him some soup with a spoon, but he soon vomited it. He was still very anxious to pass water, and a catheter being used nearly a pint was drawn off. After this he slept quietly for two hours, when he awoke and answered questions after some hesitation, and took some milk. During the night he slept fairly well, but was constantly talking in his sleep and rousing and starting up. The next day he was well but for a dryness of the throat and paralysis of the pupils; these symptoms passed off in a day or two. He said that he noticed the medicine burnt his throat and stomach, and that it caused some colicky pains, but he remembered nothing between taking the medicine and the following morning.

I think the case worthy of record, considering the large amount (ten drachms) of such a strong preparation of belladonna being taken and treatment being successful, and also the fact that there was a considerable interval between the poisoning and the first use of morphia as an antidote, although with the poison he took a grain of opium, which probably retarded its action.

Lucknow.

NOTE ON A RARE CONDITION OF THE OMENTUM.

By H. M. N. MILTON, M.R.C.S. ENG.

I WISH to add another to the cases recorded by Dr. Greig Smith and Mr. Lawson Tait respectively in recent issues of THE LANCET.[1] The tumour, a simple ovarian cyst of long standing and containing some thirty pints of fluid, was attached at three places. At its anterior superior margin was a union three inches broad with the omentum, five or six of whose vessels "resembled fat, well developed earthworms." Three inches to the left of this was a firm adherence to the abdominal wall, some six square inches in area. This I tore through with my hand before emptying the cyst, and it was only after the removal of the latter that I found a very free hæmorrhage taking place. The whole area of the adhesion presented the appearance of a cavernous angioma, or perhaps more exactly of a placenta, and it was only possible to arrest the bleeding by the use of the actual cautery. This had to be very thoroughly applied, but seemed in no way to affect the patient's rapid recovery. The third point of attachment was formed by the pedicle, which, reduced to the size of a lead pencil, presented no visible vessels. This pedicle certainly had the appearance of having been twisted, and there is no doubt that practically the whole of the blood-supply of the tumour passed through the cirsoid aneurysm of the omentum and the nævus of the abdominal wall.

Cairo.

A Mirror OF HOSPITAL PRACTICE, BRITISH AND FOREIGN.

Nulla autem est alia pro certo noscendi via, nisi quamplurimas et morborum et dissectionum historias, tum aliorum tum proprias collectas habere, et inter se comparare.—MORGAGNI *De Sed. et Caus. Morb.* lib. iv. Procemium.

ST. GEORGE'S HOSPITAL.

TWO SUCCESSFUL CASES OF LAPAROTOMY, ONE FOR DIFFUSE SEPTIC PERITONITIS OF FOUR DAYS' DURATION, AND THE OTHER FOR RUPTURED HYDATID CYST.

(Under the care of Mr. A. MARMADUKE SHEILD.)

THESE cases illustrate in a striking manner the success which may attend the prompt surgical treatment of two conditions which a few years ago were regarded as entirely "medical" and beyond the reach of help of any kind. The first case is a fairly typical one of acute perforative peritonitis, the lesion being, as usual at the age of this patient, in the vermiform appendix. We notice that Mr. Sheild attaches considerable importance to the method of flushing the peritoneum which he employed. In the second case the amount of shock and the subsequent local symptoms appear to have been out of proportion to the evidences of lesion found at the operation. The small amount of fluid in the peritoneum suggests that the shock was possibly due more to the alteration of tension in a large cyst, such as takes place when aspiration is performed, than to the effect of the fluid on the peritoneum. For the notes of these cases we are indebted to Mr. Gerald R. Baldwin.

CASE 1.—A youth aged seventeen years was admitted into St. George's Hospital on the afternoon of Aug. 10th under the care of Dr. Penrose. His bowels had been obstinately confined since Aug. 6th. On the morning of the 7th he had been suddenly seized with acute abdominal pain. On the 8th he began to vomit after all his food. On the morning of the same day he consulted a druggist, who prescribed purgatives, which considerably increased the pain. On the 10th the pain was much worse; the patient was continually vomiting and was utterly prostrated. A medical man who was called in to see him advised instant removal to a hospital. On admission the patient was collapsed, with feeble pulse and an anxious, drawn expression of countenance. His temperature was 101° F. The tongue was dry and brown. The abdomen was excessively rigid, but not much distended. It was generally tender all over, but no marked resistance was noticed in the right iliac fossa. Almost immediately after admission he was seen by Dr. Penrose and Mr. Sheild, who considered the case to be one of perforated vermiform appendix, with general peritonitis, and decided on immediate laparotomy. Accordingly the patient was at once taken to the operating theatre, and when fully anæsthetised Mr. Sheild opened the abdomen by a median incision, bubbles of gas and foul-smelling fluid escaping. The intestines were distended, congested, and covered by purulent lymph which extended even over the peritoneal surface of the diaphragm. Search in the region of the cæcum showed the mischief to have originated in ulceration and perforation of the vermiform appendix. This was ligatured near its base, the diseased portion being cut away with scissors. The peritoneal surface was thoroughly washed out with ordinary hot water poured in from large jugs. The intestines were drawn out on a towel and repeatedly washed. The abdominal wound was closed with silkworm gut sutures and antiseptic dressings applied. Next day the temperature was normal, all pain had ceased, and the patient's face was tranquil. The bowels had acted freely after a saline purge. The subsequent history was one of uninterrupted convalescence, as the temperature never rose above normal. The patient was allowed to get up on Aug. 24th and has made a perfect recovery.

Remarks by Mr. SHEILD.—Cases of recovery from diffuse suppurative peritonitis are still sufficiently rare to merit publication. The points of interest in this case are—(1) that the perforation had occurred four days prior to operation,

Digitized by Google

and (2) that practically the whole abdominal cavity was inflamed and filled with offensive fluid and gas, while the intestines were covered with flakes of puriform, adherent lymph. The rapid and easy recovery from conditions which may well have seemed desperate may be attributed to the youth of the patient, and especially to the flushing with warm water poured from large jugs, which I regard as a useful method, by which proper cleansing can be carried out. The careful management of the anæsthetic (A.C.E. mixture with plenty of air) and rapidity in operating are matters of great consideration in cases like these. The publication of this case may, it is hoped, stimulate surgeons to deal with them, and it must ever be remembered that the sooner surgeons operate in perforative peritonitis the better are the patient's chances.

CASE 2.—A man aged thirty years was admitted to hospital under the care of Dr. H. D. Rolleston on Aug. 21st. On the morning of that day he had been seized with sudden and very acute abdominal pain, which was soon succeeded by vomiting and collapse. On admission he was intensely collapsed and almost pulseless. He complained of great abdominal pain and tenderness, most marked in the right hypochondrium, where there were resistance and dulness. The right rectus muscle was tensely contracted. He vomited copiously after admission, the vomited matter being clear and watery. He was seen in the evening by Dr. Rolleston and Mr. Sheild, who decided upon exploratory laparotomy. The patient being fully anæsthetised, the abdomen was opened by a median incision. The intestines, including the duodenum and stomach, were healthy. The abdominal cavity contained a quantity of clear fluid. After some search a large prominence was noticed on the lower surface of the liver. This was aspirated, clear hydatid fluid being drawn off. Incision showed the presence of a large hydatid cyst in the liver. The fluid being evacuated, the margins of the cyst were with great difficulty attached to the parietal peritoneum, which was depressed to meet it. A long tube was introduced and the abdominal wound closed. On the 22nd the patient was slightly jaundiced and had abdominal pain; the pulse was quick and the temperature 101° F. He was very violent and restless and tore at his dressings. He was treated with small doses of morphia. The discharge was profuse and bile-stained. On the 23rd he was better and less violent. In the night he struck his attendants and required forcible restraint. The patient had done well since the last note, although there was still profuse bile-stained discharge.

Remarks by Mr. SHEILD.—Rupture of a hydatid cyst into the peritoneal cavity is a well-recognised cause of sudden collapse and death. Such cases have occurred, even in old calcified hydatids, from slight blows upon the abdomen, as in sparring. The diagnosis is always dubious, and the accident a very fatal one The present case is important in many respects. It illustrates the value of abdominal section in dubious cases associated with grave abdominal symptoms. The small quantity of free fluid points to the fact that leakage, rather than extensive extravasation, had taken place. The opening of a deeply seated cyst, and attaching it to the peritoneum, which was drawn down to meet it, was a matter of considerable difficulty. This is one of the few published cases where abdominal section has been successfully performed for ruptured hydatid cyst. There is still profuse discharge of bile-stained fluid from the tube, but the patient is in a good condition, with every chance of recovery, and, whatever be the ultimate result, the operation seemed undoubtedly instrumental in rescuing him from impending death.

ROYAL INFIRMARY, NEWCASTLE-UPON-TYNE.

FIVE CASES OF UMBILICAL HERNIA.

(Under the care of Mr. FREDERICK PAGE.)

THE results now obtained, under favourable conditions, by operation for the radical cure of umbilical hernia are well illustrated by this series of cases. It is possibly too early at present to speak of the cures as radical ones—time only will prove this; but the immense relief afforded to the patients for the time must be apparent to all readers. To operate on a case of strangulated umbilical hernia in a typical patient is a great tax on the skill and resource of any surgeon, and the difficulties such cases present are only appreciated by the experienced hospital surgeon. The patient is usually a bad subject for any operation—a big, fat woman of low vitality, suffering from chronic bronchitis and a weak heart, often a victim of chronic alcoholism, and exhausted with vomiting, pain, and loss of sleep. The hernia is usually large, with contents frequently firmly adherent to the thin sac and each other, and demands care and much patience in handling, so that the operation is of considerable duration. The mere administration of an anæsthetic to such people is fraught with danger, and when continued for an hour, or even two, adds greatly to the chances which militate against successful operation. We are strongly of opinion that in most of the cases of umbilical hernia it would be far better for the patients to undergo operation in the early stage of the condition than to run all the risks and discomforts of the mechanical treatment, with the occasional attacks of pain, obstruction, or incarceration to which they are liable. There are also always staring them in the face the risk of strangulation and the possibility of the need of an operation under unfavourable circumstances. In closing the opening in the linea alba in old-standing cases it is much more difficult to bring the edges together and keep them there than it is in the more recent ones; therefore the relapses after operation for strangulation will in proportion probably prove more frequent in this variety than in other forms of hernia or than will be the case after early operation for radical cure. For the notes of these cases we are indebted to Dr. S. Whillis, house surgeon to the Infirmary.

CASE 1.—A woman aged forty years, of the usual type, was admitted into the Royal Infirmary, Newcastle-on-Tyne, on March 30th, 1895, suffering from an umbilical hernia of eleven years' duration. It was the size of an adult head and quite reducible. The patient was much inconvenienced by its bulk. She had repeatedly suffered from incarceration of its contents. On April 3rd the sac and skin covering it were cut away, the opening into the abdominal cavity closed with quilted sutures of stout catgut, and the skin wound with fishing gut. No drainage-tube was used. The wound was dressed for the first time a week after operation, when the sutures were removed. Union took place by first intention without constitutional disturbance, and the patient left the Infirmary on April 23rd cured.

CASE 2.—A fat florid woman aged forty-nine years was admitted on April 20th, 1895, suffering from an umbilical irreducible hernia of eight years' duration. The tumour was at the time of operation as large as a full-sized football. The skin over it was discoloured and ulcerated. The woman was unable to get about and had suffered from repeated attacks of incarceration. On April 27th the operation for radical cure was performed, as described by Treves. The skin, sac, and omentum were removed. The umbilical opening was closed with quilted sutures of stout catgut, and the skin wound with silkworm gut. No drainage-tube was used. It was a long and severe operation, but healing took place by primary union without constitutional disturbance, and the patient was discharged on May 22nd cured.

CASE 3.—A woman aged fifty-two years was admitted on May 25th, 1895, suffering from a very large umbilical hernia. It was irreducible, and when she stood erect reached nearly to her knees. In the recumbent position the tumour was capable of being considerably reduced in size. Even then it remained a very large and formidable-looking tumour. The skin over it was extensively ulcerated, and below, where the hernia came into contact with the abdominal wall, there was considerable excoriation, as there was also in both groins. The ulcerated and excoriated skin emitted a foul-smelling odour. The woman was entirely incapacitated, and locomotion was almost impossible. She was very fat, and as she lay in bed the protrusion had to rest upon a pillow. She was kept in bed till the skin was rendered aseptic. On June 1st Treves operation was performed; the skin, sac, and adherent omentum were removed, weighing together nearly four pounds and a half. The opening into the abdomen was closed with thick catgut sutures, applied, not as in the other cases, vertically, but transversely. The skin wound was sutured in the same direction with fishing-gut sutures. No drainage-tube was used. The wound was dressed for the first time on June 8th, when the sutures were removed. Union took place by first intention without constitutional disturbance, but eighteen days after the operation a small abscess formed, probably from one of the buried catgut sutures. The patient was discharged on July 10th cured.

CASE 4.—A very big, fat woman aged forty-seven years

Digitized by Google

was admitted on June 11th, 1895, with an enormous strangulated umbilical hernia. There was a spot of gangrene the size of a shilling on the upper part of the tumour. The pulse was quick and the patient's general condition was such as to render any operative interference extremely unpromising. However, the sac was opened and was found to contain the greater part of the omentum and of the transverse colon, the latter being gangrenous. In addition, there were some coils of small intestine easily reducible. The whole of the gangrenous gut was cut away, and the ends were united with Murphy's button. The omentum, sac, and skin (a huge mass) were then removed and the wound closed. The patient died eight hours after the operation. A post-mortem examination showed that there had been no bleeding and that the button was in good position.

CASE 5.—A woman aged forty-three years was admitted on June 23rd with a large irreducible umbilical hernia, which was operated upon on the 24th. In this case the umbilical opening was closed transversely with buried sutures of silkworm gut and the skin wound in the same direction with silkworm gut. No drainage was employed and the wound closed satisfactorily. The progress of the case was interrupted by the formation of an ischio-rectal abscess, and the patient was not discharged till Aug. 10th, when she left the infirmary quite well, suffering no inconvenience from the buried sutures.

Remarks by Mr. PAGE.—Before the days of antiseptic surgery an operation for radical cure would have been looked upon in all the above cases as out of the question. There would have been no chance of success. In the fourth case something had to be done, and I quite believe, had the operation which was performed been done earlier, it might have been successful. Great pains were taken before and at the time of operation to render the whole surface of the abdomen aseptic, a solution of bichloride of mercury being the germicide employed for the purpose. After the final cleansing of the skin no chemical was employed, boiled water only being used for washing and flushing the wound. This is the usual practice in my wards, and union by first intention is the rule. As to the prospect of permanent cure in these cases of large umbilical hernia, I think it is very good. Speaking from a considerable experience, I consider the prospect of permanent cure to be as good as, if not better than, in the very large inguinal herniæ. The opening in the very largest umbilical hernia is seldom more than three inches in diameter, and generally it is less, nothing in comparison with the wound made for the removal of a uterine fibroid or solid tumour of the ovary.

Reviews and Notices of Books.

Nature versus Natural Selection: an Essay on Organic Evolution. By CHARLES CLEMENT COE. London: Swan Sonnenschein and Co. 1895. pp. 591.

THE object the author has in view in this work is to show that whilst there is strong evidence in favour of organic evolution, natural selection has no place in nature. Natural selection is based on the analogy believed to exist between the process of artificial selection and a process supposed to take place in nature. In the latter case the "struggle for existence" is said to be the selecting power, and it acts by securing the survival of the fittest. This is accomplished by a process of selection from those variations, however small, which are necessarily associated with sexual reproduction, leading by degrees to the transmutation of species. In opposition to this the author believes that if such a selective action did exist, other factors of evolution would anticipate its action in the transmutation of species now going on, and, further, that there is no definite proof of its action in the earlier stages of organic evolution. In his discussion of the subject Mr. Coe submits the theory of the transmutation of species by means of natural selection to certain tests, and asks, in the first place, whether there is a general consensus amongst scientific men in regard to the precise meaning of the term natural selection, since some hold that organisms are constantly varying in all directions, whilst others think that they vary only from a central line, from which a few variants diverge on either side; and some again maintain that they vary to a considerable, others to only a slight, extent. These variants are no doubt due to certain as yet unknown causes, but their preservation is due, Mr. Coe appears to think, to chance. Now, in the vast proportion of instances any variation is swallowed up and extinguished in what Mr. Francis Galton terms the regression to mediocrity. Hence, if a new and permanent variety, which is a step towards a new species, is to arise, some special modification should appear simultaneously in many individuals in a certain area. Romanes thought there was no warrant for this; Wallace, however, with far larger experience, holds that there is good reason for accepting it. Mr. Coe takes exception to the term natural selection, and shows that in reality two events are included under this term—viz., the survival of the fittest alone and the survival of the fittest and some not the fittest, and considers that these two things require differentiation. He notes also that the degree and constancy of the struggle for existence are estimated differently by different observers. He makes a good point of the alternative use of the terms "natural selection" and "survival of the fittest" as used by Wallace and Darwin, so that when a difficulty presents itself one or the other term may be employed, as may be most convenient. The argument advanced in favour of the struggle for existence is discussed at some length—viz., that since animals increase in geometrical ratio, any one animal or plant, if unchecked, would speedily overrun the world, and he meets it with the objection that for this to occur so large a series of other "ifs" must be admitted in regard to soil, climate, and other conditions as to render such multiplication almost impossible, and he holds that the output of life has been greatly over-estimated. On the other hand, he brings evidence which casts a doubt upon the constancy and severity of the struggle for existence between animals and plants of nearly allied or identical species, and shows that such competition is largely modified by the coöperation which so frequently obtains amongst the members of the animal world. He further maintains that the circumstance of one plant or one animal displacing another—as, for example, the brown Norwegian rat exterminating the black English rat or the willow displacing the watercress in the New Zealand rivers—although it may be employed as an argument for the struggle for existence and for the selection of favoured species, yet it by no means proves natural selection or the transmutation of a species by the selection of favourable variations which arise in connexion with sexual reproduction. He lays great stress upon the differences that exist between artificial and natural selection, the process in the former being strictly controlled by man with some definite object or objects in view, as beauty, strength, fleetness, or mere monstrosity; whilst in nature not only is there mergence of special characters in the general type, but death is apt to supervene and prevent the perpetuation of the special form or type that may have appeared—"the principle of Utility dominates Natural Selection with an iron rule"—and he thinks Mr. Romanes' assertion rash, that the death which takes place in nature must act with so much greater vigilance than is exhibited by the cattle breeder or the pigeon fancier, "for this death is often indiscriminate, the conditions under which the test is applied are often such that it would be rash to say whether the survivors were the fittest or the most fortunate." The only answer to this criticism, which is sound enough, is that the time is infinite, and the number of generations enormous, whilst now and again exceptional circumstances may occur favouring the preservation of life, as, for example, the comparative absence of enemies to the rabbits in Australia, where a favourable form might arise and be perpetuated. On the other hand, such chance would be greatly diminished in a region

Digitized by Google

such as that of the "tsetse" fly in the animals liable to be attacked by it. Then, again, the importance of the surrounding conditions or environment, admitted by Darwin in his later writings, is dwelt upon by Mr. Coe, especially in regard to colouration. Indeed, the chapter devoted to this subject and to instinct is one of the best in the book, the facts adduced and the argument founded upon them being well worthy of careful consideration by those who defend the doctrine of natural selection. Mr. Coe endeavours, and we think with much success, to show that under the expression "correlated variation," or the changes that take place in one part of the economy as the result of some alteration in another, a law or order of nature is implied which has or may have great influence in the permanent modification of the organism, and yet to which a proper value has not been assigned by the Darwinists. Mr. Coe makes a good point of the difficulties that surround the supposition of an animal or plant being thrown by the wind or waves on new and congenial soil, and so giving rise by successive modifications, under changed conditions, to a new species. When examined in detail such transportation is extremely difficult to conceive. It is not enough that one individual should be so transported, unless it were a pregnant female; and the necessity for appropriate food in the case of the animal, or of soil in the case of the plant, introduces almost insuperable obstacles to the survival of any given specimen. As has been well observed, even the potato has not become wild in any country, notwithstanding the large extent to which it is everywhere cultivated. Mr. Coe has brought together a large number of facts and has advanced some cogent reasoning in such a manner as not only to show that he has read and thought much upon the subject, but to demonstrate that whilst the theory of evolution by natural selection is supported by various facts, yet that it has weak points which it is well to expose, and which will require support and strengthening before that theory can meet with general acceptance at the hands of those best qualified to judge. He is very clever in pitting the statements of one observer against another, and in this way makes the Darwinists bear witness against themselves. The book as a whole is very interesting reading.

Archbold's Lunacy. Fourth edition. By S. G. LUSHINGTON, M.A., B.C.L. London: Shaw and Sons. 1895.

MORE than four years have elapsed since the previous edition of this well-known work, the editor having been unable to complete its revision owing to a serious personal accident. Since the third edition the Lunacy Act of 1891 (amending the Act of 1890) has been passed, and in the same year an important local Act for dealing with the management of the public asylums for the county and county boroughs of Lancashire. These, together with the Rules in Lunacy which were recast in 1892 and supplemented in 1893, have been incorporated in the work. Part I. consists of the Lunacy Acts 1890 and 1891, with notes and an introduction containing most of the principal provisions of the Acts and rules in a narrative form, together with the Lancashire Act and all the statutory rules and orders in force at the date of publication; but unfortunately this took place too early for the insertion of the new rules made by the Commissioners in Lunacy this year and their new regulation respecting mechanical restraint. As regards these two important matters the work under consideration is therefore unfortunately already out of date. Part II. contains all the statutes in force relating to criminal lunatics, preceded by an introduction defining what is meant by a "criminal lunatic," and giving an historical sketch of the law and a summary of the statutes now in force in a narrative form.

The appendix contains the Lunacy (vacating of seats) Act (1886) and the Idiots Act (1886). The notes appended to the clauses of the various Acts are very voluminous and contain most valuable information to those in search of explanation as to their meaning and cannot fail to be of use to any who are engaged in the treatment of persons of unsound mind. The times allowed for the due carrying out of the provisions of the Lunacy Acts, as, for example, "within," or "not more than," so many days or "clear" days are carefully computed and stated. As an instance, in Section 29 of the Lunacy Act (1890) the expression "not more than seven clear days," which often gives trouble to medical practitioners, is explained to mean seven days exclusive of the date of the medical examination and the date of presentation of the petition.

It is pointed out that Section 331 of the same Act is repealed by Section 2 of the Public Authorities Protection Act of 1893, and is replaced by Section 1 of that Act, by which an action brought by a person who has been detained as a lunatic against any person for anything done under the Act of 1890 must be commenced within six months (instead of twelve) after the act, neglect, or default complained of. The work is completed by a very comprehensive index.

A Manual of Botany. By REYNOLDS GREEN. Vol. I.: Morphology and Anatomy. London: J. & A. Churchill. 1895. Price 7*s.* 6*d.*

THIS work is based upon the manual of the late Professor Bentley, and is intended to take its place. For making the book of convenient size it is to be issued in two volumes, of which this one (the first volume) deals with the morphology and anatomy of plants, while the second one is to treat of their classification and physiology. The section on morphology is divided into chapters on the general morphology of plants, morphology of reproductive organs, and of the fruit and seed; and the anatomical section includes chapters on the cell tissues, tissue systems, and structures of stem, root, and leaf. The text is tersely written and teeming with facts, to the principal ones of which the attention is quickly drawn by the plentiful use of italics. The book is all through most liberally illustrated by clear diagrams, many of which are original. It will be found to be a useful volume for the general student as well as for those preparing for examinations.

OUR LIBRARY TABLE.

The Origin and Nature of Man. By S. B. G. MCKINNEY. London: Elliot Stock, 62, Paternoster-row, E.C. 1895.—The author of this small book says that the modern student is sometimes inclined to fancy that the last word has been said regarding the origin and nature of man, which, he goes on to show, is very far from being the case, and, we may add, is not at all likely to be the case. The author remarks that "a teacher does not deceive us when he says that protoplasm is the physical basis of life, for it is a fact that we know nothing of life, except as it is revealed by protoplasm. The unfounded and unscientific assumption comes in when it is added that the protoplasm is the formative power of living beings. The matter which is formed cannot be the formative power, and the teacher of physical science only refers to the material when he speaks of protoplasm." The book is of a metaphysical nature; it succeeds in showing the difficulty of the problems by which we are confronted and how inadequate is our knowledge to solve them; but we may fully admit all this and still point to the fruitful results which we have attained by scientific and inductive methods of inquiry and experiment. As members of the medical profession we have to deal with living beings, and, as everybody admits, life introduces an element which is unfathomable. We know a good deal of the anatomy and physiology of a cell; but, let the physicist condition his forces as he

Digitized by Google

may, he cannot make a cell or explain the mystery of the powers and properties inherent in it. We know uncommonly little of the how and why of many things—indeed, even where life is not present.

Dialogues of the Day. Edited by OSWALD CRAWFURD, with numerous full-page illustrations. London: Chapman and Hall, Limited. 1895.—A revival has taken place of late of the method of conveying stories in the form of crisply written dialogue. "The Dolly Dialogues" afforded a very successful example of this style of literature. The author enjoyed some advantages over the writers of these dialogues in that he was able to sustain the reader's interest by maintaining a continuity in the arrangement of his incident and material, which he touched with a light hand and managed to set forth with vivacity and humour, and in a tone of banter or amusing cynicism and playful irony. The present book consists of short and light sketches illustrative of the manners and customs, the foibles and frivolities, and the situations presented in modern society, furnished by numerous contributors writing independently of one another. Speaking generally, they are neat and epigrammatic and interspersed with little touches of satire, pathos, or drollery, and tricks of mental surprise which stimulate the intellectual appetite and imagination by their suggestiveness—and this is just what they should be. The dialogues are of very unequal merit, some of them being comparatively poor in conception and construction, but none of them are absolutely dull, and several are excellent and pleasantly stimulating. They require to be taken in small quantities at a time, like a savoury at dinner, to appreciate their flavour, but in that way they will be found an agreeable and light mental diversion for those convalescing from sickness. It goes without saying that the dialogues from Anthony Hope's pen are smart and piquant, but there are others which are happily conceived and agreeably written, and exhibiting the necessary *verve* and vivacity to make them good reading. We may refer to those by Miss Violet Hunt, "The End of Beginning," for example; to the smartly-conceived incident in the deftly-handled contribution by S. Squire Sprigge, "An Unrehearsed Effect"; to "The Girls he left behind Him," by Mrs. Alfred Hunt; the "Choosing a Ball Dress," by Miss Clara Saville Clarke; "Cherchez l'Homme," by A. N. Stainer, and others, as the reader of the volume will discover for himself.

Bad Air and Bad Health. By HAROLD WAGER and AUBERON HERBERT. London and Edinburgh: Williams and Norgate. 1894.—This essay, which originally appeared in the *Contemporary Review*, and has been somewhat amplified in the present reprint, is, in the words of the opening sentence, "a warning against the careless way in which the mass of people, poor and rich, ignorant and learned, allow the air of their living-rooms to be in an impure condition." The subject is presented in a manner which may be easily understood by the general reader, and the arguments are in a great many places enforced by quotations from eminent physiologists and sanitarians—a token that the authors have confidence in medical science, although they emphatically express their opinion (p. 19) that "there must be no State power of any kind placed in the hands of the medical profession." Virulent organic effluvia are throughout assumed to be the principal cause of the unwholesomeness of rebreathed air, and the authors criticise at some length the conclusions of Dr. J. Haldane and Dr. J. Lorrain Smith, whose experiments (*Journal of Pathology*, October, 1892, February, 1893) seem to show that the organic matter of the breath is comparatively innocuous. The final summing-up is: "Live as much as you can with open windows, wearing whatever extra clothes are necessary." In several respects the arrangement and mechanical execution of the book are indifferent.

A Trip to Chicago: What I Saw, What I Heard, What I Thought. By MARTINDALE C. WARD, M.D. Aberd. Glasgow: Alex. Malcolm and Co., 34, Ann-street. 1895.—This is a highly entertaining account of a month's experience in the United States during the Chicago Exhibition of 1893, including a brief visit to Canada. The author writes well, observed much, and acknowledges that he thoroughly enjoyed himself; his book is full of engravings and information and does not contain a single dull paragraph. The sea journeys out and home were between Southampton and New York; the principal cities visited (other than New York) were Montreal, Toronto, Chicago, Pittsburg, Buffalo (on the way to Niagara Falls), Newark, Philadelphia, and Washington. Dr. Ward briefly mentions that he met several of his medical brethren, diverging, however, into a few details respecting Dr. Oronhyatekha, a Canadian Mohawk chief, who studied for some time at Oxford University and subsequently returned to Canada, where he graduated as M.D. and practised medicine for some years.

Wright's Improved Physicians' and Surgeons' and Consulting Visiting Lists. 1896. Bristol: John Wright and Co. London: Simpkin, Marshall, Hamilton, Kent, and Co., Limited.—These lists are in two forms—one with so many pages assigned to a month, and another distinguished as the perpetual form. In the latter, pages for visits are put up in the *perpetual* form, the particulars of date to be filled in by the practitioner at the top of the page. There is a convenience in being saved the trouble of making out a fresh list every week as in other lists, but many prefer this to a list running on for a month or a longer time. The books are neatly bound in fine leather, and a great variety of useful tables, convenient for ready reference by the busy practitioner, are given at the beginning of either volume.

The Cause and Prevention of Cholera. By E. H. HANKIN, M.A., Chemical Examiner and Bacteriologist to the North-Western Provinces and Oudh, Fellow of St. John's College, Cambridge. Second edition. Agra: Printed at the *People's Herald* Press. 1895.—This is a second and enlarged edition of Mr. Hankin's little pamphlet. In a tract of this nature (mainly intended for the instruction and guidance of the natives of India) it is inevitable, as its author says, that some things should be stated dogmatically, but evidence in favour of each of the opinions he has expressed will be found in papers which he has already published or is about to publish. Mr. Hankin accepts the comma bacillus always associated with cholera as its cause, and he briefly tells us why and how it gets into water, and the conditions under which it grows and multiplies or dies therein. He deals with the disinfection of wells and with several of the native customs and habits in a useful and discriminating way, and touches upon the various methods in which the micro-organism may gain access to the body and how best to guard against it. The pamphlet is written in an eminently simple, clear, and practical style.

A CHOLERA HOSPITAL FOR CARDIFF. — Mr. Thompson, of the Local Government Board, held an inquiry at Cardiff last week in reference to the application of the town council for leave to borrow £2450, the cost of erecting a cholera hospital on the Flat Holm island in the Bristol Channel. The existing building is a shed capable of holding six beds, and three years ago, when cholera was prevalent on the Continent, a large marquee was erected to afford greater space. The expenses will be borne by Cardiff and Barry. The new building would comprise two six-bed wards and a nurse's room, with the requisite sanitary arrangements and a crematorium. A farmhouse exists on the island which would be used as an administrative block, and the small existing ward would be used in case of necessity as an isolation or auxiliary ward of the proposed new pavilion.

Analytical Records
FROM
THE LANCET LABORATORY.

MARVINO GRAPE WINE.

(DOWDEN AND CO., LTD., ST. PAUL'S-LANE, BOURNEMOUTH; AND 8 AND 9, ST. MARTIN'S-LANE, LONDON, E.C.)

WE have no doubt of the genuineness and wholesomeness of this wine, despite its very moderate price. It is produced, it is said, from imported grapes, and can be sold at the rate of 12*s.* per dozen (quarts). It possesses a peculiar, somewhat aromatic flavour, is light in character, and well suited for use as an ordinary wine at mealtime. Analysis gave the following results: Alcohol, by weight, 10·92 per cent.; by volume, 13·52 per cent.; proof spirit, 23·70 per cent.; extractives, 2·32 per cent.; mineral matter, 0·17 per cent.; total acidity, reckoned as tartaric acid, 0·74 per cent.; and sugar, 0·28 per cent. As will be seen, it is commendably free from excess of sugary constituents and is not unduly acid. In short, its composition is analogous to that of a sound and genuine Burgundy of a mild and agreeable type.

PORTABLE SOUPS.

(THE PORTABLE FOOD COMPANY.)

These preparations are intended as portable rations for soldiers in the field or for travellers or explorers, where vegetables are scarce and transport difficult. We have received three kinds—(1) consolidated mulligatawny, (2) consolidated Scotch broth, and (3) consolidated pea-soup. Each is contained in a tin "cartridge" about two inches long by about an inch and a half wide, open at both ends. Prepared in the manner directed a really palatable soup is obtained, the appearance, taste, and composition of which are seemingly identical with freshly-prepared soups of every-day formula, except that they contain, of course, desiccated vegetables. They afford, therefore, a convenient and acceptable resource for food under the circumstances already indicated.

KOCIDE.

(THE KOCIDE CO., CLARENCE-ROAD, LEEDS.)

This is a brown powder possessing a disagreeable but not very powerful smell of tarry matters. It is for the most part insoluble in water, the insoluble portion serving probably as a suitable absorbent of the active agent, whatever that may be. It is acid in reaction and contains much sulphate; ether extracts a trifling amount of yellow oil, and on submitting the powder to dry distillation a small quantity of oil came over. In the case of good carbolic powders we should expect to expel under these circumstances at least 10 per cent. of tar acid. Kocide is claimed to be a powerful germicide, but we do not gather that any evidence based on bacteriological experiment has been obtained on this important point.

VARIOUS MEDICATED SOAPS.

(D. AND W. GIBBS, CITY SOAP WORKS, E.C., AND ABBEY CHEMICAL WORKS.)

According to a series of tests made in our laboratory these soaps may be commended, not only because of the excellent quality of the soap employed, but because also of the fact that they are reliable in regard to the various therapeutic agents contained in them. We have received ten in number, as follows:—1. Sulphur soap (10 per cent. sulph. præcipitat. B.P.). 2. White birch tar soap (10 per cent. pix liquida e betula alba). 3. Ichthyol and tar soap (3 per cent. ichthyol sulph. amm. and 5 per cent. pix. liq.). 4. Eucalyptol soap (5 per cent. ol. eucalypti rectif.). 5. Sulphur, camphor, and Balsam of Peru soap (5 per cent. sulph. precipitat. B.P., 5 per cent. spiritus camphoræ B.P., and 3 per cent. Balsam of Peru). 6. Corrosive sublimate soap (½ per cent. hydrarg. perchlor. B.P.). 7. Borax, naphthol, and sulphur (freckle) soap (5 per cent. natr. biborac., 2½ per cent. naphthol pur., and 10 per cent. sulph. præcipitat. B.P.). 8. Boracic acid (shampoo) soap (5 per cent. acid. boracic. B.P.). 9. Salicylic acid and sulphur soap (3 per cent. acid. salicyl. B.P. and 10 per cent. sulph. præcipitat. B.P.). 10. Carbolic acid ("surgeon's") soap (20 per cent. pure carbolic acid crystals). Careful search for excess of alkali was attended with negative results except a slight indication in No. 7, which contains biborate of soda. The composition of the corrosive sublimate soap (No. 6) is not so uniform as it might be, since patches of the perchloride occur across the surface. They become more obvious when they blacken by exposing the soap to the vapour of sulphide of ammonium. These soaps one and all, however, are without the slightest injurious action upon the skin, while doubtless they act effectually in accordance with their medicated composition.

AMMONOL.

(THE AMMONOL CHEMICAL CO., NEW YORK.)

Ammonol is the name given to ammoniated phenyl acetamide. The ammonia is evidently loosely combined, since a sample of the slightly yellowish amorphous powder which was submitted to us smelt strongly of ammonia. It accordingly behaves as a stimulant as well as an antipyretic and analgesic, thus differing from the almost numberless coal-tar derivatives and antipyretics with which modern pharmacology is deluged. Ammonol has been used chiefly in the relief of rheumatism and neuralgic pains, and in the treatment of the sequelæ of alcoholic excess. The presence of ammonia in a more or less free state gives it additional properties as an expectorant, diuretic, and a corrective of hyper-acidity. Ammonol is also prepared in the form of salicylate, bromide, and peptonate.

ADEPS LANÆ, N.W.K.; PURE NEUTRAL WOOL FAT.

(THOMAS CHRISTY AND CO., 25, LIME-STREET, E.C.)

There are certain important features about this particular preparation which render it of additional value as an emollient and basis for ointments. Adeps lanæ, N.W.K., is specially refined, and consists of pure neutral wool fat minus the harder fatty constituents. Its melting point is therefore lower, and the preparation is consequently more soft and supple, so that it will absorb water if required to the extent of three times its weight, and is readily absorbed by the skin; moreover, it is a non-rancifying fat and perfectly neutral in reaction.

DAVICINI'S PURE STERILISED MILK.

(C. S. COX AND CO., NEW YORK, AND 4, FENCHURCH-AVENUE, E.C.)

On analysis this milk proved to be only of moderate quality. Thus it contained 3 per cent. fat, 9·46 per cent. of non-fatty solids, and 0·7 per cent. of mineral matter. The method of sterilisation is undoubtedly satisfactory since the milk was in an excellent state of preservation, and its flavour was good and freer than is usually the case from "boiled" taste. The composition of this otherwise excellent milk would have been more satisfactory if the proportion of fat had been greater, the amount found being close on the line that separates a poor from a rich milk. Objectionable preservatives were absent.

WHOLE MEAL WHEAT FLOUR.

(R. VARNDELL, WAVERLEY MILLS, FARNHAM, SURREY.)

We have submitted this flour to examination and find, in accordance with the description, that it consists of finely ground whole meal with only a part of the bran present in a comminuted state. It contains an excellent proportion of albuminous principles, as can be easily ascertained by suspending the flour in water in a muslin bag, when the starch washes away, leaving the gluten and bran behind. It is evidently prepared from wheat of superior quality, its flavour is rich, and its aroma good.

THE LANCET.

LONDON: SATURDAY, SEPTEMBER 28, 1895.

THERE seems to be little fear that for some time to come those who are engaged in the working out of the details of new methods of treatment will, in spite of the fact that they are doing so much, find their occupation gone. Of this we have abundant evidence in the account of the Preparation of Antirabic Serum and the method of Determining its Strength by Professor TIZZONI and Dr. CENTANNI, the conclusion of which appears in our present issue. This investigation is of special interest since, should the efficacy of the serum treatment of rabies be proved, new factors become available for consideration and application to the method as a whole, and the scope of the application of the treatment will be enormously increased.

As early as 1889 BABES and LEPP appear to have indicated the possibility of obtaining some protection against rabies by injecting the blood of an animal inoculated against rabies (by PASTEUR'S method) into one previously or afterwards infected by the virus. Although much work has since been carried out on the same lines there was little practical outcome from it all until BEHRING, followed by ROUX and ABONSON, had worked out the method of treating diphtheria and tetanus by means of antitoxic serum. The experience gained by TIZZONI and his colleagues in the preparation and use of anti-tetanic serum has now, however, been applied to the treatment of rabies by a somewhat similar method; and if all the results recorded are confirmed by fuller and independent observations there can be little doubt that a great advance has been made in the treatment of hydrophobia. Instead of carrying out the greater part of the preparation of the antidote within the body of the patient by a process of "vaccination," TIZZONI and CENTANNI follow the usual plan of preparing this substance in an animal from which it is conveyed to the animal to be treated in the blood serum as a vehicle. In place of using PASTEUR'S method of protective "vaccination" for the animals from which the serum is to be obtained, they, by a process of peptic digestion, attenuate the virus to be used. What the exact action of this digestion may be is as yet somewhat doubtful; whether it diminishes the activity of the poison-secreting organisms, kills them, or "attenuates" the ferment produced by them is a subject for careful experiment. At all events, the activity of the virus is said to be so far modified that considerable doses may be injected at a comparatively early stage of the process, and animals that have been so injected withstand the action of the more virulent virus within a comparatively short period. This part of the process is carried out upon sheep, which may be "vaccinated" again and again. These animals always retain a certain immunity, which can be increased from time to time by fresh injections of virus, the activity of the serum corresponding to the amount and virulence of the virus injected. In these points the method of obtaining the serum is much like that by which the tetanus and diphtheria antitoxic serums are prepared. This serum, when mixed in definite quantity in a test-tube with a lethal dose of canine or fixed virus, and then injected into a rabbit, so neutralises the poison that neither is there any increase in quantity of the virus nor are the slightest signs of rabies developed, even though the animal be kept under observation for four or five months. More important still, when an inoculation with a lethal dose of the poison is made, a comparatively small quantity of the serum serves to neutralise its effect if injected at once, and even if delayed until the end of the first half of the incubation period the amount required to be given has only to be multiplied some six or eight times. In this respect the serum has great advantages over those used in the treatment of diphtheria, in which the dose has to be multiplied some 20 or 100 times, and of tetanus, in which the increase of the dose must amount to from 1000 to 2000 times in the later stages of the incubation period. Leaving out of consideration the prophylactic properties of this serum, which could only be of use in the case of those who are constantly in contact with dogs, the success of the experiments as regards early treatment is from a practical point of view of very great importance. It is possible, by drying, to prepare a "permanent" form of this serum which will, if kept from air and light, remain active for a long period. It is very portable, is readily dissolved, and may be used by anyone who is capable of sterilising a subcutaneous injecting needle and syringe. The treatment, therefore, can be commenced almost as soon as the patient has received the bite, as it is not necessary that he should leave his home or his own medical attendant, with the result—and we assume that these experiments are to be fully relied on—that the patient at once receives a quantity of the antitoxic material, which under the PASTEUR method could only be manufactured in the body of the patient himself, and then in quantities sufficient to neutralise the infective material, say, after the second half of the incubation period.

One other most important point brought out by these researches is that, just as in the case of tetanus poison, the virus has a distinctly selective action; it seems to exert its full effect on the central nervous system or on some parts of it. Bearing this fact in mind, and injecting the doses of serum in special positions, it is found that it is necessary to inject much smaller doses of the serum under the dura mater of the brain than if the injections are made into the substance of a nerve; whilst when the injection is made subcutaneously a still larger dose is necessary than when the serum is injected at either of the above sites. It is evident that the serum must act in one of two ways. It may act as a direct chemical antagoniser of the virus. The results of other experiments, however, appear to put this out of court, and there remains the theory that the serum so acts upon the nerve centres, probably the cells, that with its aid they are able to carry on their functions in the presence of even considerable quantities of virulent material. Where the serum is injected subcutaneously a large proportion of the active material is wasted in fortifying cells which do not really need to be protected, whilst the nerve cells only participate generally in the benefit conferred. When

Digitized by Google

the serum is injected into the substance of a large nerve the protective agent at once finds its way into channels which communicate fairly directly with the cerebro-rachidian lymph system, so that a larger proportion of the active protective agent comes into direct contact with the central nervous system. When, further, a subdural injection of serum is made we have the most direct contact possible. Just those parts which are in need of strengthening are brought into contact with the protective material, and the best results are obtained. TIZZONI and CENTANNI claim that they have worked out all these different points and that their results are now beyond question. Allowing for some, or even a considerable, amount of bias in the matter, there would still remain evidence, we think, of sufficient value to encourage them and others to persevere in this work. At present cases come up for treatment which, from the severity of the wounds and the amount of virus left in them, we can never hope to cure by the PASTEUR method, valuable as that method is when the cases are brought under treatment sufficiently early, and when the patient does not succumb too rapidly to the virus left when the bite is made. Some of these cases, if the experimental results are accurately recorded, would undoubtedly yield to the serum treatment, especially as that treatment can be commenced with the least possible delay. One point more must always be remembered when reading this paper and in determining the value of the results obtained and recorded by the authors. BEHRING, in determining the strength of his antitoxic serum, is able to make artificial cultures of his poison-producing organisms, after which he has only to separate the poison from these organisms in order to obtain a poison of constant strength which has no power of reproducing itself. TIZZONI and CENTANNI, on the other hand, are handicapped by the impossibility of making artificial cultures of their rabic virus, whilst, unless the process of peptic digestion or some similar process is carried out before the virus is injected, this material remains capable of reproducing itself for some considerable time after the injection has been made. Altogether, the paper is full of suggestions. Much of the work has evidently been carefully done, and if we cannot accept all the conclusions arrived at it is because the statements are so far reaching and important that it would be unfair, even to the investigators, to accept them without very full and independent corroboration.

As we are at this period much concerned with educational regulations and meditating on the best use that medical students can make of their "hasting days" of opportunity the time is fit for giving a little attention to the arguments in favour of devoting six months of the fifth year to pupilage under a general practitioner. The first thing to be said in favour of this use of six months is that it is in accordance with the regulations of the General Medical Council. The following is the regulation which will be found on page 592 of the Students' Number of THE LANCET: "4. The fifth year should be devoted to clinical work at one or more of such public hospitals or dispensaries, British or foreign, as may be recognised by any of the medical authorities in Schedule A of the Medical Act (1858), provided that of this year six months may be passed as a pupil to a registered practitioner holding a public appointment or possessing such opportunities as shall be satisfactory to the medical authorities." This regulation deserves the serious attention of every student who has come to his fifth year and is within measurable distance of the personal responsibilities of private practice. It is one thing to act as a clinical clerk or a resident physician in a hospital, and have all one's work revised and checked by the physician or surgeon in charge, and quite another thing to have all the responsibility of diagnosis and treatment in one's own hands. Besides, the class of cases is different. Private practice varies much from hospital work, and it is no more possible to learn its nature and general management from hospital practice than it is to learn the details and requirements of hospital practice from the routine of general practice. We are without definite information as to whether much or little use is made of this half of the fifth year by medical students. But the whole regulation is so good and so well expresses the views of those who have studied the defects in our present system of medical education that we think it desirable to direct the attention of advanced students to its suggestions.

The great purpose which the Council had in framing the resolution was evidently to emphasise the fact that the main use of the fifth year was to concentrate all previous learning into practical channels and to bring the student into contact with actual living cases of disease. Work is to be exclusively clinical. The student is to get it where he can, in foreign hospitals or home ones, and in the practice of registered practitioners. There is one condition attached alike to hospitals and practitioners—that they shall be approved by the medical authorities to whom the candidate applies for a qualification. The condition is a reasonable one. The regulation is the only one of the regulations of the General Medical Council which explicitly recognises the registered practitioner, as such, as a coöperator in the great process of medical education. It is otherwise in the law. In the training of a solicitor articled pupilage is the principal part of education. In the process of medical education it used to be a prominent feature, but it is no longer so. This regulation is the only recognition by the Council of the principle that was carried far in the system of medical education that ruled up to forty years ago. But general practitioners should take note of the regulation and of the conditions it includes. It should be an object of ambition in every registered practitioner whose practice or whose appointments are favourable for the purpose to take pupils—i.e., advanced medical students—and initiate them in the art of seeing patients and detecting and curing their diseases.

The General Medical Council did well, we think, to leave to the examining bodies the recognition of the fitness of both hospitals and general practitioners as sources of medical instruction. But there is no reason to think that the medical authorities will be illiberal in recognising the claims of any medical man whose appointments or whose standing in the profession are

Digitized by Google

such that he is likely to be able to give students opportunities of seeing common diseases in their continuity and of watching their treatment. Practitioners may well be willing to accept pupils who are of the standing implied in the regulation. They will become teachers of medicine in an important sense by so acting. They will derive benefit as well as confer it. They will learn from such pupils as well as teach them. They will keep in touch through them with the latest improvements in diagnosis and treatment, and so preserve that freshness of mind which is the mark of a good practitioner and the great condition for preserving interest in work that is otherwise apt to grow monotonous and mechanical. But it is the student himself who should be most benefited by this limited pupilage. Supposing him to choose his principal well, the advantage must be great in every aspect. Every detail of his principal's work will be a lesson to him: the method of seeing patients; the dispensing arrangements, supposing the practitioner to have such; the common diseases, which so largely constitute medical practice, and the ready means of recognising and relieving them; the detection and notification of infectious diseases; the personal knowledge of patients and their families, so different from the casual intercourse with unknown strangers in hospital practice; vaccinations; labours; clubs; private patients of every rank treated with equal consideration; and the social position and importance of his principal—all these will be lessons that will be eminently helpful to the student in the early days of his own practice. Even the errors of his principal will not be without their advantage to him. It remains with students themselves to use the facilities afforded by this regulation or to disregard them and to commence practice in that ignorance which has made many men, who would shine in the class-room and be able assistants in the operating theatre, feel awkward in the commonest emergencies. Hospital practice can only be learnt in hospitals, and private practice from a good registered practitioner, and six months are all too short for the latter lesson.

As the season draws near for sufferers from phthisis to go abroad for the winter it may not be inopportune for us to remind the profession, as we have often done before, of the responsibilities which the medical adviser has in this matter, and of the dangers which may attend advice given in any routine or offhand fashion or without adequate knowledge. Climatic treatment is a large subject which is beset with peculiar difficulties and needs special study if it is to be applied with discrimination and effect. It means much to the patient, is usually productive of decided benefit or injury, and the failures of such treatment often entail much misery on the patient and the patient's friends, and a corresponding amount of discredit upon the medical adviser. There are few catastrophes in practice more deplorable than to send a patient suffering from advanced or subacute phthisis on a long sea voyage or to some distant health resort only to perish miserably far from the comforts and consolations of home. Such a result may no doubt be in some cases unavoidable and may be reckoned among those "calamities of medicine" which we must all be prepared to face. But, on the other hand, there is no reason why a result of this kind should be anything but the rare exception if the medical adviser is thoroughly well posted in the principles which should regulate this department of practice. It is only fair to point out that the fault not uncommonly rests with the patient rather than with his adviser. Some patients go abroad without medical advice or in direct contravention of it, and it need hardly be said that it is most unjust to hold the profession responsible for the results which follow.

The first question which the practitioner has to consider in dealing with phthisical patients anxious to try a change of climate is whether any change is desirable or whether the patient should not rather remain at home. It is comparatively easy to define the cases in which the patient may be freely advised to try climatic change and those in which he must be dissuaded from what is a hopeless venture; the real difficulty is with the cases that are on the border-line. We may say with confidence that if the amount of disease is small, localised, and not progressive; if there are little or no wasting and fever; if the general health, and especially the integrity of the digestive system, is well maintained; if there are no complications; and if the patient is of a cheerful disposition and not averse to the prospect of foreign travel—then there can be little hesitation in advising climatic change, and the only question will be to decide what change would probably be most beneficial. On the other hand, if the damage to the lung is extensive and progressive, if there are much wasting and fever, if there are marked constitutional breakdown and serious complications, then climatic change must in the great majority of such cases be forbidden, or, if permitted at all, only to a limited extent and merely as a palliative measure. These principles are, we think, clear and do not require argument or proof. The difficulty, as we have said, is chiefly with the intermediate cases. What amount of pyrexia or wasting should be held to contra-indicate climatic change in a case otherwise calling for it? In a doubtful case shall we attach more weight to the nature of the local lesion or to the constitutional symptoms? How far shall we allow the family history to govern our decision, or the existence of special symptoms, such as hæmoptysis? We do not imagine that these questions can be answered very definitely, and much must always depend upon the practitioner's insight, common sense, and capacity for penetrating to the real nature of the case before him; but we may throw out a suggestion or two. The medical adviser called upon to deal with these cases will seldom regret relying to a considerable extent upon the thermometer. An evening temperature that is persistently above 100° F. should, as a rule, be held as a contra-indication for distant travel. Anything like severe pyrexia must be regarded as an absolute contra-indication. The practitioner should, also, attach much weight to the known history of the case, and should therefore be much on his guard with cases that he sees for the first time and of which he has no precise history. A case may present a very small local lesion, and yet the temperature or the general constitutional enfeeblement may point to the

Digitized by Google

probability of a rapid progress of the disease, and hence to the futility of climatic change. Family history may also be important in this regard, but it is difficult to appraise it correctly. It is probable that its importance has been often over-rated. The stage of the disease is, in our judgment, of much less importance than the amount of lung involved and the type of the case. Thus, a case in the first stage with progressive lesion and much fever may be wholly unsuitable for climatic change, whereas a case with a single cavity, where the constitutional state is good, often does well. Much weight should be attached to the patient's capacity for taking and assimilating ample nourishment. The maintenance of nutrition is the keynote of the successful treatment of phthisis, and the prognosis may be allowed to be materially affected by the state of the digestive system. Hæmoptysis or night sweating may be proper grounds for delay, but do not in themselves constitute any contra-indication for climatic change. It is not true that patients are more prone to hæmorrhage at the high altitude stations or at sea than they are at home.

Every suitable opportunity should be taken of impressing upon patients that the proper time for climatic change is when the disease is threatening rather than actually declared. It is, we conceive, the simple fact, deplorable as it is, that at present in the vast majority of cases the proper time for applying climatic treatment with effect is allowed to pass, and that treatment is commonly reserved for a stage of the disease when its success is always precarious and its failures are many. On the other hand, its success in the early incipient stage of the malady is often great and brilliant. Early diagnosis is of supreme value in this matter and cannot be too earnestly insisted upon. We have not space in this article to enter upon the second part of the subject—viz., climatic change being deemed suitable, what shall be the nature of that change? This is a very large subject on which it would not be possible to say anything of value with sufficient brevity. The sea voyage, the high altitudes, and the dry inland plains like those of South Africa now divide the title of supremacy. They are all most useful in their place, and we are gradually learning to distinguish the cases most suitable to each.

Annotations.

"Ne quid nimis."

IS THE QUALITY OF BREAD DETERIORATING?

IF the only object of the Bakers' Exhibition held this week in the Agricultural Hall were to place before the public a good, honest loaf of bread, we should look upon it as an annual benefaction of no mean importance to the community. We have no desire to underrate the value of trade exhibitions; indeed, we do not doubt that they have a bracing effect upon business; moreover, traders are brought together who exchange ideas, and they may derive the advantage of seeing new machinery, appliances, and articles necessary for the advancement of their business. All this is right and proper in its way, but are the interests of the public equally studied? Methods may be improved so far as an increased economy to the manufacturer is concerned, but does the consumer really derive any benefit from this, or is the product any the better? In the case of bread, for example, we are not the last to appreciate the improvements effected in the details of its manufacture, as instanced in the introduction of ingenious machinery by which from beginning to end the loaf is untouched by human hand; but all this is no guarantee that the loaf has been made from honest materials. Machinery can incorporate very inferior wheaten flour or potato flour, alum, and indifferent and perhaps foul yeast into the composition of the dough with greater subtlety probably than human hands; it may even produce a more attractive loaf, an apparently larger or bulkier loaf, lighter in texture, with a tempting glaze, but this speaks nothing, or perhaps a good deal, of the quality or the nature of the interior. Is it not the experience of most bread-eaters—and who is not a bread-eater?—that the average bread supplied by the London baker, the tin and the cottage loaf, for example, bears no comparison in regard to flavour and nutritive qualities with the unpretending home-made bread made with flour the pedigree of which is known? And yet, given the same materials—flour of good quality, preferably English grown, pure yeast, and common salt—why cannot the baker produce with all the new and improved appliances at his disposal a loaf which shall possess that delicious wheaten and biscuit-like flavour of real home-made bread? It is a serious matter, because, doubtless, a very large proportion of the public do not eat bread in the quantity that they should because of the indifferent flavour and of the non-appetising character of the stuff largely sold in our bakers' shops. They lose, therefore, all the excellent dietetic advantages of one of our most complete foods. We fear the public are much to be blamed; they persistently demand a chalky white, anæmic loaf—one which has the aspect of offering a "lot for the money," but made, perhaps, from an inferior foreign flour employed to make the loaf larger. As long as this sort of demand continues there is no doubt that the supply will be equal to the occasion. The remedy, however, rests with the consumer; let him demand bread made with honest and the best materials, let him obtain a guarantee from his baker that it is made with superior and really nourishing wheat, and not with the poor stuff that is imported in large quantities from abroad. Then he may really enjoy his daily bread and return with delight to a source of sustenance which ministers to his bodily needs far more completely than any other food, because if the wheat from which it is derived is of good quality, of unimpoverished and unstunted growth, it repairs the bony structures, builds up the tissues, and supplies healthy and invigorating materials to the blood. Evidently Nature had an important object in view when she endowed wheat with an attractive flavour, and it is nothing short of an outrage to take this property away and to attenuate its nourishing qualities by sophistication or other detestable means. Last week we had occasion to comment upon the fraudulent practices which recent inquiry has shown to exist amongst the wholesale grocery trade; these are bad enough, but, at least, let us demand bread that is worthy of the name of the "staff of life."

THE SEXUAL NOVEL.

THERE has of late been a tendency for writers of fiction to produce works treating almost entirely of sexual subjects; in fact, the so-called "woman novel" is concerned with nothing else—unless, indeed, it be subjects that grow out of the original one, like hereditary syphilis. These books are generally bad, immoral, wrong-headed, and physiologically incorrect. One of the silliest of its class is "The Woman who Wouldn't." We received a copy of this work for review, and almost coincidently with it a little book called "Baby Buds." We give the authoress of the latter every credit for wishing to do her best

Digitized by Google

of bread, for example, we are not the last to appreciate improvements effected in the details of its manufacture interested in the introduction of ingenious machinery which from beginning to end the loaf is untouched by human hand; but all this is no guarantee that the loaf has been made from honest materials. Master can incorporate very inferior wheaten flour or potato flour, and indifferent and perhaps foul yeast into the composition of the dough with greater subtlety probably than human hands; it may even produce a more attractive and apparently larger or bulkier loaf, lighter in texture with a tempting glaze, but this speaks nothing, or perhaps only, of the quality or the nature of the interior. How the experience of most bread-eaters—and who is not?—can testify—that the average bread supplied by the London baker is the tin and the cottage loaf, for example, bears no comparison in regard to flavour and nutritive qualities with the commonest home-made bread made with flour the pedigree of which is known? And yet, given the same materials—flour of good quality, preferably English grown, pure water and common salt—why cannot the baker produce with all the new and improved appliances at his disposal a loaf which shall possess that delicious wheaten and nutty flavour of real home-made bread? It is a serious matter, because, doubtless, a very large proportion of the public do not eat bread in the quantity that they should because of the indifferent flavour and the non-appetising character of the stuff largely sold at our bakers' shops. They lose, therefore, all the undoubted dietetic advantages of one of our most complete foods. We fear the public are much to be blamed; they persistently demand a chalky white, anæmic loaf—one which has the aspect of offering a "lot for the money," but made, perhaps from an inferior foreign flour employed to make the inferior As long as this sort of demand continues there is no hope that the supply will be equal to the occasion. The remedy, however, rests with the consumer; let him demand bread made with honest and the best materials, let him insist on a guarantee from his baker that it is made with sound and really nourishing wheat, and not with the poor stuff that is imported in large quantities from abroad. So he may really enjoy his daily bread and return with zest to a source of sustenance which ministers to his bodily needs far more completely than any other food, because the wheat from which it is derived is of good quality and impoverished and unstunted growth, it repairs the waste structures, builds up the tissues, and supplies healthy invigorating materials to the blood. Evidently Nature has an important object in view when she endowed wheat with an attractive flavour, and it is nothing short of an outrage to take this property away and to attenuate its nutritive qualities by sophistication or other detestable practices which recent inquiry has shown to exist among the wholesale grocery trade; these are bad enough, but at least, let us demand bread that is worthy of the name—the "staff of life."

THE SEXUAL NOVEL

THERE has of late been a tendency for writers of fiction to produce works treating almost entirely of sexual matters in fact, the so-called "woman novel" is occupied with nothing else—unless, indeed, it be subjects that are of the original one, like hereditary syphilis. These are generally bad, immoral, wrong-headed, and logically incorrect. One of the silliest of its kind "The Woman who Wouldn't." We received a copy [illegible] and almost coincidently with [illegible] We give the author

to explain to children a subject which needs no explanation, and about which they will learn quite soon enough; but we wish to point out that Opalia, the fatuous heroine of "The Woman who Wouldn't," is just the sort of character that would be produced by being nourished on "Baby Buds" in childhood. And what does the authoress of "Baby Buds" do? She is talking to a child aged four and trying to explain "where our new little baby came from." After a great deal of beating about the bush and talking about plants and pollen she says: "Mammals or birds have no need of bees or moths to transfer the pollen substance from the male to the female, for they can approach one another for that purpose. ..... Indeed, they do so approach at certain times that the ovules of the female may receive some of the pollen substance. How this fully comes about you can hardly understand until you are older." This, of course, is quite true; then what was the use of beginning, and to a child aged four, too? The "woman who wouldn't" married her Alan "only in church," as she explains, and on their wedding night she says, "I trust you so much that I want you to come to my room and help me to un——" dress, she was going to say. ..... Then she added "pack." Eventually, as might have been expected, her husband took up with another woman, and then the woman who wouldn't became the woman who would and did. It is undesirable that the writer of "Baby Buds"—evidently a well-meaning, refined, and delicate-minded woman—should try to explain matters to her children at such an early age; those of the age of twelve or thirteen may be told certain things. With regard to works of the class of "The Woman who Wouldn't" it is a pity for any writer to sit down and write outside of his or her environment. The stories in the Decameron, the various Contes, the Restoration comedies, and the Georgian novel are amusing and wholesome compared with many of our nineteenth century writings. But they were written in the thoughts and manners of the time, without any idea of advertisement. Their authors had no missions or high moral aims, and these works, "Pamela," "Joseph Andrews," "The Country Wife," and others, will live when the women who didn't and couldn't and wouldn't are totally forgotten.

SEATS FOR SHOP ASSISTANTS.

MANY years have elapsed since it was first proposed to provide seats for the use of shop assistants, and the proposal has not been made in vain. Its result, nevertheless, has been by no means equal to the reasonable expectations of its supporters. A number of large firms throughout the country have, it is true, afforded their employés this very moderate concession to the demands of health and convenience. It is probable, notwithstanding, that at least as many have made no such provision. Yet the project is in itself entirely reasonable. It is no measure of mere indulgence, but a serious answer to the constantly repeated warnings of experience. It has been proved over and over again that the still common practice which obliges young people to stand about hour by hour throughout weeks and months of a business life is injurious to health. No quadruped—certainly not the biped man—is capable of safely enduring such prolonged neglect of his physical necessities. The whole order of nature teaches the same lesson. Every organ and every tissue submits to regularity and by frequent rhythmic change alternates energy with rest. It is absurd to pretend that a like system of reliefs is incompatible with business. With method and practice any difficulty could be overcome and a habit be acquired which would directly promote alertness by preventing overstrain. Seats behind the counter are not merely the comfort and the privilege of assistants. They constitute an effectual safeguard of the interest of employers, since they secure these a service more spontaneous in proportion as it must in the very nature of things more capable. It is hardly necessary to draw a clinical diagram of the evil consequences of long-continued standing. Most educated persons know enough of the structure of their bodies to teach them much and to explain why strain of muscle, nerve and spine, varicosities, and other circulatory disorders form the constant sequel of fatigue thus wantonly courted. The opposition we have to contend with is only in part due to ignorance. It is partly also the result of thoughtless want of sympathy, and it is probable that even this difficulty has been exaggerated. The shopping public is less indifferent to the comfort of its helpers than has been supposed, and we are convinced that employers who would candidly trust its consideration and would treat their employés in the intervals of their service have no reason to fear the transference of their custom. As regards the kind of seat there may be wide differences of opinion, but we should suppose that some form of fixed support contrived with a little forethought in arrangement would be found to be the most useful and the least obstructive. We may refer to our readers' remembrance that in our issue of Aug. 2, 1880, we referred to a seat invented by Messrs. Colman of Glendenning of Norwich, and St. Martin's-le-Grand, London which was simple, inexpensive, and took up but little room. It would be interesting to know by how many firms some such seat has been adopted.

THE LONDON WATER-SUPPLY AND THE RECENT DROUGHT.

THE report of the official water examiner on the condition of the metropolitan water-supply during the month of June 1895, contains some observations of unusual interest in connexion with the scarcity of the East London supply. The Major-General A. de Courcy Scott—reverting to his report for the month of June, in which he stated that the East London Water Company had found it necessary to reduce the supply of water pumped into their district in consequence of the rapid depletion of the storage reservoirs which had been in progress—now reports that from July 15th the supply was still further restricted, the water having been shut off from all mains except those provided with fire-plugs during from twenty-four to twenty-two hours out of each twenty-four. The supply to three-fourths of the district was consequently received for only two or three hours daily. The remaining services being fitted with fire-plugs were kept charged under statutory obligation. In consequence of a large number of houses in the poorer districts not being provided with cisterns, the substitution of an intermittent supply of two or three hours duration for the constant supply, which had been universal, "resulted naturally in serious inconvenience and considerable danger to health owing chiefly to the impossibility of flushing the waterclosets and drains as required." The depletion of the company's storage reservoirs between May 27th and July 15th appears to have proceeded at the rate of about twelve million gallons per diem on the average. Calculations show that the East London Company "were taxing the resources of the river [Lea] to the utmost extent," bearing in mind the requirements of navigation, and it would appear from the reports that "the necessity for rigorous limitation of the quantity pumped into the district was imperative, and that the measures adopted were not more drastic than the occasion required." The gradual increase in the volume of the River Lea which ensued after a fall of rain at the end of the month, and later, has enabled the company to lengthen from time to time the period during which water is turned on, and it is stated that it now extends from about 6 A.M. to 8 P.M. Since sea

Digitized by Google

have occurred during which the September flow of the Lea has been exceedingly small it would not be prudent, adds the official water examiner, to revert to a constant supply until a reasonable reserve of water has been accumulated in the reservoirs. It is perfectly clear from all this that when drought happens—this summer being, of course, somewhat exceptional—one portion of London at any rate, and a very densely populated portion, may at any moment reach the extent of its resources in regard to water-supply. There is no doubt that the position was at one time most serious, and the real and dreadful terrors of a water famine were imminent. In so vital a matter as this is the merest probabilities and possibilities must be taken into minute account and ample provision made against the very worst that may happen. The immediate question is not so much one of administration, but rather whether the present undertakings are capable of yielding an adequate, or rather a bountiful, supply in any hands whatsoever and under any strain of circumstances. The East London Company, it appears, had not the wherewithal to supply water owing to the unusual drought, and it is to this point that inquiry should be directed. In regard to quality the metropolitan water-supply during July was satisfactory, as is attested by Professors Frankland, Dewar, and Crookes.

THE FRENCH FORCE IN MADAGASCAR.

THE latest accounts from Madagascar regarding the health and sanitary condition of the French expeditionary force in that country appear to be most unsatisfactory. The troops in front occupying the uplands are comparatively healthy, but a large amount of sickness prevails among those in the rear on the lowlands. There are upwards of 3000 sick in the hospitals, and the mortality and invaliding rates have already been very high. In addition to the prevalence of active malarial disease, necessitating hospital treatment, those who have suffered from it and other climatic disorders become anæmic and enfeebled in health, and, as General Duchesne says, "drag along and languish without being able to recover." The only course left open, he adds, is to send them home as promptly as possible. "This is the advice of the Director of the Medical Service, and it is also mine." Unfortunately, however, this course has been attended, as might have been expected, with a very serious loss of life during the hot season in the Red Sea, on board the overcrowded troopships transporting the invalids to France. It is said that General Duchesne had orders not to send any soldiers home from Aug. 20th to the commencement of October. The road-making proved to have such a disastrous effect on the health of the troops that it has been discontinued. A strong feeling of dissatisfaction prevails in France at the amount of sickness and mortality that has occurred, owing, it is thought, to the grave mismanagement of the expedition. No proper arrangements were made for the landing and transport of stores, large quantities of which were consequently lost or had to be abandoned; the soldiers disembarked in the thick cloth uniforms they wore in Europe, and had to march inland heavily laden with their kits, haversacks, and cooking tins; the system of native carriers broke down from the carriers becoming disabled and sick or deserting; there was great difficulty in the matter of supplies; and the hospital service was quite inadequate to the strain imposed upon it. It is also stated that the force in the field was hampered by the action of the French War Office and other departments in connexion, for instance, with the utilisation of the hospitals and sanatoria at Réunion. A second hospital ship has, it is understood, been asked for. Be all this as it may, the descriptions given of the overcrowding of the hospitals and the insufficiency of military medical officers, nurses, and sick attendants disclose a sad state of affairs. One correspondent says that three of the field hospitals were crowded with sick. While they are only intended to accommodate 250 each, the hospital at Suberbieville contained 600 and that at Ankobaka had 1000 patients, the beds in the latter having been placed one above the other. The distance from Andriba to Antananarivo will, it is estimated, occupy fifteen or sixteen days' march, and provisions for twenty days are being accumulated at the former place. General Duchesne hopes to be, as he always anticipated, at Antananarivo at the end of the present month, and in that case we may soon expect to hear much better accounts of the expeditionary force. Of course, a large military expedition in an extremely hot, malarious, and difficult country, without roads or even paths, cannot be undertaken without grave risk to health, and under the very best organisation and arrangements there may be an unexpected amount of sickness with topographical obstacles and climatic difficulties to be overcome. We have served an apprenticeship in petty wars in hot and malarious climates, and have not invariably conducted some of our own little expeditions with such an amount of wisdom and foresight as to be entitled to cast a stone at our military neighbours; but we do not understand how it was that the French War Office failed to have more thoroughly "prospected" the country and made better arrangements for the exceptional character of the campaign than they seem to have done. The expedition to Madagascar seems to have been undertaken too hastily and before the necessary arrangements had been thoroughly thought out and completed, but there is, nevertheless, no adequate reason for the great revulsion of feeling from one of elation to one of extreme depression which is said to have taken place in France.

TWO DEATHS BY LIGHTNING.

DURING the August storms two deaths from lightning took place on the Sussex Downs. The first occurred during the violent storm on Aug. 10th near the village of Alfriston in the eastern part of the county. Here, as in the case recorded in THE LANCET of last week, a man and woman were walking together. They had been to show an acquaintance his way on the Downs, and although there was no thunder when they started they were caught in the heavy storm which followed. They were walking together arm-in-arm when a flash of lightning and a peal of thunder were stated by the woman to occur simultaneously. Her husband, a carter named Foord, said "Oh," and they both fell to the ground, linked as they were arm-in-arm. The woman appears to have lain unconscious for some time. Her own version is that when she "came to" she found she could not walk, so she crawled home for assistance. Her husband was afterwards brought home dead. The woman says that when she rolled over she noticed "sparks" come from under her, and for some days she was confined to her room by illness. The dead man was seen by Mr. Hugh Wallis on the spot where he fell. There was a discolouration on the left side of the head, and a good deal of blood flowed from the nostrils. There was no wound or abrasion. The hat, which was found some eight yards from the body, showed an irregular cut which had severed the band and completely penetrated the felt. A knife and key, with threepence in coppers, were found in the waistcoat pocket, but bore no marks to show that they had been in contact with the lightning. The grass at the spot where the body fell was scorched. A case which occurred later—on Aug. 22nd—is more clear. Three men were working a steam plough at Lancing, near Worthing, when a storm, which had appeared to be but trivial, suddenly increased in violence. The cultivator was making its last journey, a man named Ransom being in charge, when the two men with the engine were alarmed by a vivid flash, and shutting off the steam made for the nearest

Digitized by Google

shelter, one of them shouting to Ransom to "clear out" too. One of the drivers said the flash seemed to strike his engine, causing a rattling sound, and then to run "right on to the top of Ransom." Both the drivers got safely to shelter and expected that Ransom had done the same, but the hovel in which they took refuge hid the machinery from sight. The storm lasted half an hour, when the men found Ransom dead, still on the seat of the cultivator, but in a lying position and, so they said, black in the face. Mr. C. M. Kempe found only a slight abrasion on the forehead, from which a little blood was flowing. There was no sign of blackening as from burning, and no fracture.

DIPHTHERIA IN LONDON.

THE deaths from diphtheria registered in London last week, were 37, being two below the corrected decennial average for the corresponding week of the years 1885–94, and fewer than the records of the three preceding weeks, and with one exception fewer than the weekly records for a long time past. The three preceding weeks had seen 40, 38, and 55 deaths respectively. The deaths occurring last week included 4 each belonging to St. Pancras and Greenwich, and 3 each to Mile End Old Town and Lambeth. All the deaths were in persons under twenty years of age, and the great majority in children under five years of age. The diminution in fatality last week was in no wise attended by any like falling off in amount of the disease, for both the fresh cases and the admissions to hospital showed an increase. Of the latter, there were 114 as compared with 86, 78, and 105 in the preceding weeks; and the patients remaining under treatment on Saturday last numbered 665, a total practically identical with the numbers for the last five weeks. In the Outer Ring of London there were 16 deaths registered from diphtheria, and of these 6 occurred in West Ham district and 3 in Hornsey subdistrict.

THE MODERN PRINCIPLES OF SEWAGE PURIFICATION.

SIR DOUGLAS GALTON in his presidential address at the recent meeting of the British Association at Ipswich, among other topics included in his analytical *résumé* of the progress of physical science in the interval between 1831 and the present time, adverted to the subject of sewage purification. Owing to the difficulties entailed in thickly settled districts and the extent of land required for the direct application of sewage to soil, and the large amount of sludge that had to be dealt with after the chemical treatment of sewage, it was long contended that the simplest plan was to turn the sewage into the sea, and this was accordingly done in localities where it could be carried out. It was not until the chemist called to his aid the biologist and came to the help of the engineer, says Sir Douglas Galton, that a scientific system of sewage purification was evolved. Dr. Frankland many years ago suggested the intermittent system of filtration, which Mr. Baldwin Latham was one of the first to adopt. But the valuable experiments made by the State Board of Health in Massachusetts more clearly explained how by this system micro-organisms might be utilised for the purpose. To effect this we require, says Sir Douglas Galton, in the first place, a filter about five feet thick of sand and gravel or of some material which affords numerous surfaces or open pores; and, secondly, that after a volume of sewage has passed through the filter an interval of time be allowed in which the air necessary to support the life of the micro-organisms is enabled to enter the pores of the filter. Thus, this system is dependent upon oxygen and time. Under such conditions the organisms necessary for purification are sure to establish themselves in the filter before it has been long in use. Temperature is a secondary consideration. Imperfect purification can invariably be traced either to a lack of oxygen in the pores of the filter, or to the sewage passing through so quickly that there is not sufficient time for the necessary processes to take place. And the power of any material to purify either sewage or water depends almost entirely upon its ability to hold a sufficient proportion of either sewage or water in contact with a proper amount of air.

PATHOLOGICAL ANATOMY OF MULTIPLE SCLEROSIS.

DR. O. HUBER has recorded in *Virchow's Archiv* the result of an examination of the central nervous system in a case of this strange and obscure disease. The examination seemed to indicate that the disease consists essentially in a parenchymatous degeneration of the nervous tissue. It was found that, in recently affected spots especially, there was widespread disappearance of the nerve fibres without any greater changes in the interstitial substance than could be accounted for by the changes secondary to the disappearance of the fibres, so that the sclerotic patches must, in this case at least, be regarded as due to the disappearance of the nerve fibres, with consequent proliferation of the interstitial substance. No explanation is furnished of the absence of secondary degeneration, which would naturally be expected to follow from the presence of the islands of sclerosis in the tracts of the spinal cord.

FORBIDDEN FRUIT.

A PECULIAR case of death occurred last week in the Royal Infirmary, Liverpool. The patient, a boy aged about fifteen years, had been operated on for radical cure of hernia by Mr. Rushton Parker and was going on well after the operation. His father, however, paid him a visit, and on leaving gave him some grapes unknown to the nurse and against the rules. In the night he was taken suddenly ill, and by the time the house surgeon reached him he was dead. A necropsy was made, and his larynx was found to be full of grape skins, which had caused death by asphyxia. It is strange that friends will be guilty of such mistaken kindness in serious cases, and seem to delight on visiting days to take for the patients fruit and sweetmeats which are injurious to those they are so anxious about. It is a well-known fact to hospital surgeons that their patients are frequently worse after a visiting day, although the greatest vigilance may be observed by the nurses in attendance.

HOW SCARLET FEVER IS SPREAD.

THE repeated failures of prosecutions under Section 126 of the Public Health Act, 1875, would seem to suggest that some modification of that section is desirable. As a rule such actions fail because the sanitary authority is unable to prove that the person suffering from the infectious disease, or being in charge of a person so suffering, was aware of the true nature of the disease; but recently a case tried at the Colchester Police-court was dismissed because the medical attendant who had notified that certain members of a family were suffering from scarlet fever failed to prove that they were so suffering when the notification was sent to the medical officer of health. The family resided in the parish of Coggeshall, in the Braintree rural district, and five of the children were in succession attacked with scarlet fever, the fact being duly notified by the medical attendant. When all were convalescent and four had finished "peeling" the whole family moved to West Mersea, a small watering-place on the Essex coast, in the Lexden and Winstree rural district. Neither the clothing of the patients nor the house in which they had resided had been disinfected. When Dr. Carr, the

Digitized by Google

medical officer of health for the Braintree rural sanitary district, found that the family had gone to West Mersea, he advised the medical attendant to acquaint the medical officer of health for that district of the fact. This he did by sending five notifications to the effect that the children were suffering from scarlet fever. Dr. Cook, the medical officer in question, at once visited West Mersea and found the children coming up from the beach in the company of other children. He did not examine the patients, but reported the facts at the next meeting of his district council. A prosecution was ordered, and when the case was heard before the Colchester Bench Dr. Cook said that he could not assert of his own knowledge that the children were actually suffering from scarlet fever. The medical attendant said that as the children had practically finished "peeling" it was questionable whether there was any danger of infection, and that he notified the cases as a precautionary measure. The case was thereupon dismissed. As the medical man who notified did not attend the patients whilst at West Mersea, and expressed such grave doubt as to whether they were still suffering from an infectious disease, the validity of the notification is open to question. It would have been better had the notice of removal been sent by Dr. Carr in his capacity of medical officer of health. Under the circumstances the Lexden and Winstree district council had no option but to prosecute, and it is to be regretted that they failed to secure a conviction. If children who have suffered from scarlet fever can be removed with impunity to a watering-place before they have ceased to desquamate and before their clothing has been properly disinfected the risk of spreading the infection amongst the community is greatly increased, and either some better definition is required of the words "suffering from any dangerous infectious disease" or there should be some appeal allowed against a decision of this character. Possibly a prosecution under Subsection 3 of Section 126, which refers to the transmission of infected clothing without previous disinfection, would have been successful, as the evidence of the medical attendant could then have been dispensed with. Such a miscarriage of justice is to be deplored, but it can scarcely be wondered at, considering the nature of the evidence.

IS COLOUR-BLINDNESS A CASE OF ATAVISM?

A RECENT writer, M. Dubois, throws out a suggestion that will probably be new to most of our readers. It is recognised by astronomers that there are three classes of stars—first, the bluish-white stars, of which Sirius and Regulus are examples. More than half of all known stars belong to this class. In these stars combustion is at its maximum, and their atmosphere consists of super-heated hydrogen and certain metallic vapours. The second class, or yellow stars, has for typical representatives Capella and our own sun. They are less hot than the first class, and the hydrogen lines in their spectrum are not so conspicuous as in the case of the white stars. This class contains about 33·5 per cent. of all known stars. The third class are the red stars, and of these Betelgeux is the representative. They are in a later stage of cooling than the second class, and the violet rays are deficient. This class includes about 8 per cent. of known stars. From these known facts it is conjectured that colour-blindness (or insusceptibility to the red rays of light) may possibly be a case of atavism—a "negative inheritance from that time long ago when the eye of our ancestors was not yet sensitive to red rays, which were almost entirely wanting in the white stage of the sun." This is a startling theory, but it suggests a plausible explanation of what is such a mysterious fact—viz., that colour-blindness should so uniformly take the form of insusceptibility to the red rays. Atavism is without doubt a principle of wide application, and may be fairly relied upon to explain many apparently inexplicable facts. We will not venture to pronounce upon the correctness of its application in the present instance, but at least the theory is a bold and ingenious one, and, if accepted, would tend towards that unifying of knowledge which is the aim of science. Colour-blindness, regarded as an isolated phenomenon, is mysterious, but if it be a case of atavism it takes its place in the scheme of ordered knowledge.

RHEUMATISM AND APPENDICITIS.

DR. BEVERLEY ROBINSON of New York, in the *New York Medical Record* of Sept. 14th, argues in favour of an etiological connexion between rheumatism and appendicitis. He admits that he has seen no immediate relation between an attack of acute rheumatism and an attack of appendicitis, though others have reported such an experience. But he says: "When it comes to the milder and, according to some, perhaps less characteristic symptoms of rheumatism, these I have repeatedly observed in patients who have had one or more attacks of appendicitis," and "I have seen more than one patient who subsequent to attacks of appendicitis had decided articular manifestations, and during many years of this rheumatic localisation the appendicial region has remained entirely free from any inflammatory disease." Dr. Robinson is also thoroughly convinced of the frequent efficacy of salicin or salicylates to relieve pain and avoid suppuration, though he uses also local applications, rest in bed, light diet, and if necessary, but only on the failure of these means, morphia or codeia. The point is one of great scientific and practical interest, which we commend to the attention of our readers.

THE COST OF ISOLATION IN LONDON.

THE comments made by the coroner, Mr. W. E. Baxter, in a case at Mile End, where a scarlet-fever patient was sent back home by the Asylums Board officials on the ground that there were no vacant beds, raises a question of the utmost importance. Time was when there was difficulty in inducing parents and friends to allow their infectious sick to be removed to the Asylums Board hospitals, but that is now a thing of the past, and the demand now made on these establishments altogether exceeds the accommodation available, notwithstanding the fact that an enormous expense is constantly being incurred in the erection of new hospitals, some professedly temporarily and others admittedly permanent. In the case immediately under consideration it transpired that patients have had to wait five or seven days before their turn arrived for admission to hospital both during epidemics of diphtheria and prevalence of scarlet fever. Now, if all these cases needed removal from their homes in the interests of public health, and if in all cases adequate isolation could not be carried out where the patients sickened, then we must candidly admit that they ought to be isolated elsewhere. But we have no evidence that these facts do apply to all cases, and we know that a very heavy burden is gradually being placed upon the ratepayers in order to provide means of hospital isolation for infectious diseases. According to the recently issued report of the medical officer of the Local Government Board the following notifications were received in the administrative county of London in 1893: small-pox, 2948; scarlet fever, 37,974; diphtheria, 13,470; enteric fever, 3746; continued fever, 217. For how many of these cases, wellnigh reaching 60,000 in number, should the Metropolitan Asylums Board provide at the public cost? That is the real question which is raised; and if the Local Government Board deals with the representation of the coroner in the proper way, it will be to elicit, in the first instance, something of the circumstances of the

Digitized by Google

persons and households which are in question as making demands on the Asylums Board to receive their sick. The public interests must stand first, but we need evidence to show what are the main public interests concerned.

THE UNITED STATES MAILS AND THE TRANSMISSION OF BACTERIOLOGICAL SPECIMENS.

BACTERIOLOGICAL examination is such an essential feature in the diagnosis of certain diseased conditions that those who place obstacles in the way of its performance are incurring a somewhat grave responsibility. We learn, however, from the last bulletin of the New Jersey State Board of Health that up to July 2nd the Postmaster-General had refused to modify the order of the United States Postal Department of June 1st, 1896, which excludes from the mails "disease germs, discharges of any kind from diseased persons, or other things of like character, no matter how securely put up." This position has apparently been maintained in spite of the fact that Dr. Henry Mitchell, secretary of the New Jersey State Board of Health, intimated to the Postmaster-General the proposal of the Board to establish a bacteriological laboratory, and submitted to him a specimen mailing package similar to those used in France. Furthermore, the New Jersey Medical Society has expressed its opinion that diseased tissues for bacteriological examination can be transported without endangering the health of persons handling the packages. The bulletin from which the above information is derived expresses an opinion that if all those engaged in bacteriological study would join in an effort to make the subject clear to the postal officials all would be well; but we should have thought that the opinion of the New Jersey Medical Society would be sufficient to effect the desired modification. Unfortunately, the Postmaster-General merely states that he does not "deem it expedient to modify the present rule," so that we are precluded from discussing the objections to the proposal.

THE FRENCH ARMY MEDICAL SERVICE.

EVER since 1882 the Service de Santé of the French Army has been practically autonomous, the command of all transport, as well as of the *personnel* derived from other branches and temporarily attached for duty, having been vested in medical officers by virtue of the law of March 16th in that year. It seems, however, that this condition of things is displeasing to the combatant arms, and, according to an article published in the *Bulletin Médical* of Aug. 4th by Dr. Noël, an organised attempt is being made to deprive the medical corps of all control over the men composing the detachments, who have been instructed to pay attention to orders from their own officers alone. The first outcome of this retrograde movement, we are told, is the issue of a circular from Artillery headquarters, laying down the mode of progression to be followed by ambulances. On no account are they to leave the public roads, and the pace they are driven at must never exceed a walk. Should a gutter intervene the utmost care must be exercised in crossing it. Dr. Noël is very indignant, and rightly so, we think, at this attack on the medical officer's prerogative. In Germany, Austria, and Russia, where the feudal spirit is rampant, where caste prejudice persists, and where the fighting element looks upon itself as something superior, such a state of affairs might be expected, but France has a right to demand a more enlightened procedure. As long as medical officers are held responsible for the successful administration of their service it is only just that they should be endowed with supreme authority therein, and also with means sufficient to enable them to accomplish their task. The new state of things is in flagrant contradiction to both the spirit and the letter of the law of 1882. It remains for the members of the Senate and Chamber to record their opinion of a measure whereby a permanent source of dissension is introduced into the medical service, which robs medical officers of all power of accomplishing the duty entrusted to them by their country, which, in fine, simply kills the medical service, while paving the way for disorders and disasters, should war break out, such as not even the terrible year 1870 could equal. There is one point in Dr. Noël's article to which many readers will take exception. Amongst the new armies of Italy, Switzerland, and Japan, where there are no superannuated prejudices to be overcome, and where consequently the medical departments are autonomous and successful, he places that of England.

HEALTH RESORTS AND INFECTIOUS DISEASE.

IN Dr. Niven's last quarterly return on the health of Manchester he points out that, although each autumn there is fresh evidence that children taken to "health resorts" frequently contract scarlet fever and other infectious diseases, it is astonishing that heads of families should continue to manifest so little solicitude as to the freedom from infection of the quarters which they select. Visitors are, he remarks, entitled to a guarantee that the seeds of infection shall not be present in apartments offered, and he reminds the people of Manchester that at seaside places where notification is in force visitors may obtain reliable information from the medical officer of health. In reference to this point it appears to us that in some large health resorts inquiries such as these by visitors entering the town might add very materially to the work of the sanitary department. To assist persons resident in Manchester in the selection of a holiday resort Dr. Niven has had the last quarterly return of the Registrar-General placed in the Public Health Office for reference, and he draws attention to the information contained in Table VIII. as to the infectious disease mortality in the principal watering-places of Great Britain during the quarter ended June 29th. We shall be much interested to hear what use has been made of the opportunities so offered by Dr. Niven.

THE DIFFUSION OF SMALL-POX.

THERE was a decided drop in the number of fresh cases of small-pox coming to light in the metropolis last week as compared with recent periods. In the four weeks ending Aug. 10th there had been a weekly average of over 70 notifications of the disease in London, followed by an average of 60 in the succeeding four weeks, this smaller average being mainly the result of the decrease in the last fortnight of the period. Indeed, in the four weeks ending on Saturday last the average number of cases each week was only just over 30, the attacks of last week having been but 21, a sensible decline taken in conjunction with previous weeks. Of the 523 notifications, as to the locale of which in the eight weeks ended Sept. 7th details are to hand, no fewer than 304 were in six sanitary areas situated in the east and south-east of London. The admissions to hospital last week were 23, against 36, 25, and 42 in previous weeks, and the patients remaining under treatment on Saturday last numbered 271, a total which has been steadily diminishing since it stood at 342 on Aug. 24th. Two deaths were registered, one being assigned to Shoreditch and the other to Greenwich, one being that of a vaccinated adult and the other that of an adult concerning whose vaccination no statement is forthcoming. Manchester had further experience of small-pox last week, one death being registered and 8 attacks being recorded. The disease had for some time been confined to the Openshaw district, but has now got beyond it. In the borough of Oldham the attacks in the

Digitized by Google

fortnight ending Aug. 24th were 11, 1 less in the next two weeks, and only half that number in the fortnight ending last Saturday. The decrease is satisfactory. In Dublin the admissions to hospital in the second week of September were 9 in number, an increase over the numbers of several previous weeks. The death of an unvaccinated infant was registered. Three discharges took place and 18 patients remained under treatment, all the convalescent cases having been sent away from Kilmainham Small-pox Hospital.

SANITARY CONVENIENCES AT RAILWAY STATIONS.

THOSE who are accustomed to make long railway journeys must be frequently impressed, not to say disgusted, with the filthy condition of the sanitary conveniences at the railway stations in this country, and must be led to reflect as to whether such conveniences are ever visited by the sanitary inspectors of the districts in which they are situated. At the more important stations, where a small charge is made for the use of the closets, there is often little or nothing to be said against the accommodation; but in smaller stations, where apparently the cleansing of the closets is left to a porter, who has in addition numerous other duties to perform, the condition of affairs is such as to frequently preclude the use of the closet for the purposes for which it was intended. The position and construction of such closets render the presence of light impossible, and in consequence it is difficult without the aid of artificial illumination to properly estimate the filthy conditions which obtain. Further, owing to the absence of sunlight and ventilation, the drying process is much delayed, and for several hours after the floor has been cleaned it is undesirable to deposit thereon any small articles of luggage, while the want of a peg or nail for the suspension of such articles still further complicates matters. In some cases improvement is impossible short of entire reconstruction; but in numerous instances, which we have ourselves examined, the introduction of a window together with improved ventilation would bring about a very radical change. The flushing apparatus is frequently out of order, owing not so much to misuse as to defective construction; but this point could, of course, be easily remedied. When regard is had to the agency which badly flushed and filthy closets may play in the dissemination of enteric fever, it is obviously a matter of no inconsiderable importance that improvement in the direction indicated should be effected, and we venture, therefore, to commend the sanitary conveniences at railway stations to the combined attention of sanitary authorities and the railway companies.

DIPHTHERIA AND SCHOOLS.

THE village of Bedlinog, near Merthyr, having a population of about 1500, mostly colliers, has during the late spring and summer been visited by an epidemic of diphtheria, 78 cases having been notified between April and August, besides a few which appeared from time to time during the preceding winter months. The houses are for the most part well built of quarried stone and are dry and airy, the sewerage is good, and the water-supply is the same as that of Merthyr. In Powell-street, however, there is a row of damp, dilapidated wooden structures appropriately called the "huts." They are not connected with the public sewers, but have privies with cesspits in their backyards. In these, as might have been expected, the incidence of the disease was heaviest, and here occurred the first of the continuous series which constituted the epidemic, but the sporadic cases between December and March were all in other parts of the town. The connexion of the schools with the origin and spread of the infection was evident from the fact that 61 of the 78 cases were those of children attending school, the remaining 17, whether over or under school age, having in every instance been subsequent and secondary to the former, alike in the huts and elsewhere, while the conditions of the schools were amply sufficient to account for the outbreak. Though spacious and in other respects well arranged, the sanitary conveniences consisted of trough closets, automatically flushed and connected by glazed pipe drains, without traps, with two cesspits sunk in the pervious sandstone rock, with no steining or cement lining, into which the fluid part of the sewage percolated so freely that they never required emptying. In fact, it had not been deemed necessary to provide any aperture for access or ventilation, and as a consequence each periodical discharge of the flushing tank displaced an equal volume of foul air, which escaped by the sole exit—the open drain-pipe—into the closets. Though the conditions of the huts were such as would tend to intensify the disease when it broke out among them, this did not take place until April, and even then the first cases were those of scholars who were less exposed thereto than those children who never left their homes. This outbreak, whether it had its origin in the schools, or, as the medical officer of health is inclined to think, in the huts, suggests the grave question of the responsibility for the scandalous violation of the elements of sanitation in the former. In the first place, of course, the architect employed by the local School Board may have been to blame, but all plans have to be approved by the Education Department; and we may well ask how it came about that the authorities of the Department could pass or allow to be passed plans which provided for the saturation of the subsoil with sewage and involved the periodical discharge of volumes of foul gases into buildings attached to the schools.

AT the centenary of the London Missionary Society, to which we beg to offer our hearty congratulations, it is noticeable that speakers from every part of the field of operations make generous allusion to the part played by medical missionaries. This was especially so in the speeches referring to Madagascar by the Rev. James Richardson of Antananarivo, Madagascar, and the Rev. G. A. Shaw, F.Z.S., Farafangana, Madagascar. The founders of the society little thought in 1795 of this element in the work, which is destined to bear still more fruit.

THE work of reconstructing the premises of the General Medical Council—now the property of the Council itself—is proceeding as rapidly as possible. But it is, perhaps, a little sanguine to expect that it will be completed in time for the November meeting. The drainage is being placed on a much more satisfactory footing than before, and perhaps the necessity for this was not anticipated when the alterations were commenced. This and other causes may interfere, but every effort, we believe, is being made to realise the wishes of the Council.

ON Tuesday, Oct. 1st, Sir James Paget will present Dr. Hughlings Jackson with his portrait and a piece of plate. The testimonial, which has been widely subscribed for, will be given at 3 P.M. in the Library of the London Hospital Medical College, where also a replica of the portrait is to be placed.

WE regret to have to announce the death of Professor Bardeleben, which occurred on Sept. 29th at Berlin. We shall publish an account of his life and work in an early issue.

Digitized by Google

REPORT OF THE MEDICAL OFFICER TO THE LOCAL GOVERNMENT BOARD, 1893-94.[1]

[FIRST NOTICE.]

THE valuable collection of reports and scientific memoirs that is issued annually in the report of the medical officer to the Local Government Board has come to be regarded, and rightly so, as one of the most important publications of the year. There is always much that is instructive in the details of the carefully conducted investigations upon epidemic disease furnished by the medical inspectors, whilst the laboratory work of Dr. Klein and his colleagues which constitutes the section of the report entitled "Auxiliary Scientific Investigations" deals with the more recondite problems of etiology, to the solution of many of which these papers have largely contributed. The admitted value and excellence of the series of volumes which has thus accumulated makes the want of a good index to them more evident. It might perhaps be superfluous to have an index to each volume; but the publication from time to time of a general index would be a great boon to those who are engaged in preventive medicine. The present volume constitutes the supplement to the twenty-third annual report of the Local Government Board and deals with work prosecuted in the year 1893-94. The ably written report by Dr. Thorne Thorne summarises with precision and exactitude each of the several subjects treated in detail in the appendices. These embrace a variety of topics, such as enteric fever, diphtheria, epidemic skin disease, cholera, moorland waters in relation to lead poisoning, and furnish much information, some of which confirms and corroborates previously accepted ideas, whilst other portions open up new and suggestive lines of inquiry. In the present notice it will be sufficient to briefly indicate the outlines of these reports, which deserve to be studied in detail.

The customary statistics relating to vaccination in England and Wales appear in the forefront of the volume. They refer to the primary vaccinations amongst the 914,079 infants whose births were registered in 1891, and they show that there is a progressive increase in the numbers of those "unaccounted for." This class now form 13·4 per cent. of the total number of births, the percentage being 16·4 in the metropolis and 12·9 in the provinces. An explanation for this growing evasion of the vaccination laws may be in part explained by the decision taken by many boards of guardians to abstain from prosecution of defaulters pending the report of the Royal Commission. Thus year by year it is becoming more difficult to reinforce compulsory vaccination if, as may surely be anticipated, the commission reports in that sense. A glance at the statistics shows that the chief towns in which vaccination is most neglected, as denoted by the high percentage of children in the "unaccounted for" or "postponed" list, are—

	Per cent.		Per cent.
Gloucester	84·7	Barrow-on-Soar	78·1
Wellingboro'	83·2	Luton	77·1
Keighley	83·1	Blaby	76·7
Northampton	80·2	Halifax	74·9
Leicester	79·9	Kettering	73·6
Oldham...	78·7		

whilst at Saddleworth, Thrapston, Loughborough, Eastbourne, and Falmouth the figures stand at from 60 to 70 per cent. The singularly variable proportion of children certified as "insusceptible" to vaccination in different districts is, perhaps, explained by the fact cited by Dr. Thorne Thorne—that at the Lambs Conduit-street station there has not been a single failure of the vaccination to take out of 81,500 persons primarily vaccinated there during a series of years, for although a small percentage failed on the first attempt there was only one failure on the second, and that was removed by a third attempt. The inference that "insusceptibility" is coterminous with "inefficiency" seems obvious.

Amongst the reports of the medical inspectors selected for detailed publication are four of no slight importance dealing with the subject of "waterborne typhoid." The memorable epidemic of enteric fever at Worthing in the summer of 1893 was investigated by Dr. Theodore Thomson, whose report, fully illustrated by plans and maps, shows clearly that the outbreak in Worthing proper was related to the accidental inrush of water into a heading in course of excavation connected with one of the large wells in the chalk that formed the supply to this portion of the borough. The water thus introduced into the pure supply had penetrated through soil contaminated by leaking sewers. A fortnight after this occurrence enteric fever, which had not existed in the place during the past year, appeared, and this outbreak formed the starting-point of an epidemic lasting from May to November, with marked exacerbations in July following an abatement at the end of May and beginning of June. Altogether there were no fewer than 1257 attacks in "Worthing" alone in a population of 15,300. West Worthing and the neighbouring villages of West Tarring and Broadwater were also the seat of the disease; but only the last-named derived (in part) its water from the "Worthing" wells, the supply to West Worthing and West Tarring being distinct. Moreover, the outbreak in these districts was much later in its appearance and far less severe than in the "Worthing" division of the borough, and no clear connexion could be traced between the two. Dr. Maclean Wilson reports on an outbreak of enteric fever in Chester-le-Street between October, 1892, and March, 1893, when 58 cases and 4 deaths occurred in a population of 4864. In this limited area, where many dwellings were the reverse of sanitary, investigation showed that the cause of the outbreak was referable to contaminated water-supply. For with only two exceptions each of the invaded households received their water from the Chester-le-Street Company, which supplied about 650 out of 1100 houses, the remainder being supplied by the Consett Company. The water came from the Stanley Burn, which above the intake receives the sewage from several villages, and co-incidently with the outbreak in Chester-le-Street, four cases of enteric fever had occurred in some cottages which drained directly into a tributary of the Stanley Burn about three miles above the intake. It is further pointed out that the sand employed for the filtration of this water-supply is derived from the banks of the Wear at a point below its reception of the sewage of a large population. Dr. Bruce Low investigated the conditions associated with the prevalence of enteric fever in the Vale of Pickering and at Malton from November, 1892, to January, 1893. The villages especially implicated were Nunnington and Ness in the Kirkby Moorside rural district, and Butterwick and Brawby in the Malton rural district. Here again there was ample evidence of sewage contamination of the River Rye, for the disease only attacked those households which took their water-supply from this stream, whereas those taking water from wells escaped. This river in its course receives the sewage of villages, and particularly of the town of Helmsley, between which and Nunnington also were fields bordering on the river upon which was spread the "town manure," including night soil from Leeds. This interesting report further deals with Malton, where prevalences of fever and diarrhœa have been shown to supervene upon seasons of flood in the Derwent. The well that supplies the place is apt to be invaded by water from that river which is joined by the sewage-contaminated Rye four miles above Malton. Dr. Bruce Low also reports on enteric fever in Trentside villages, proving beyond question that this important river, which affords a water-supply for domestic services to a large rural population, is contaminated by sewage, especially from the towns of Gainsborough and Newark: thus, of 192 attacks of enteric fever in that district, no fewer than 167, or 86·9 per cent., occurred among a population of less than 6000 dwelling in villages, of which the main water-supply was drawn from the Trent or from canals similarly contaminated. The harmfulness of the Trent water was also proved in the case of Newark itself, where of 297 cases of enteric fever during three years and a half, 78·5 per cent. were among those who consumed Trent water, and 21·5 per cent. among those who took their water from local wells. It is satisfactory to learn that since then Newark has been provided with a constant supply from the new red sandstone. It is not surprising, in face of these facts of the use of contaminated rivers and the supineness of local authorities in dealing with the evil, to find Dr. Thorne Thorne give expression to the following forcible statements. He says (p. 14):—

"In my report on cholera in England during 1893 I pointed out that of the 64 localities in which cholera appeared in this country the disease was limited in 42, or

[1] Twenty-third Annual Report of the Local Government Board, 1893-94. Supplement containing the Report of the Medical Officer for 1893-94. London: Eyre and Spottiswoode. 1894. Price 13s. 4d.

Digitized by Google

nearly 60 per cent. of the whole, to one single attack; and this was the case although as regards the majority of the attacks the disease must be looked upon as having been true cholera of the Asiatic type, whether it be judged by its clinical symptoms, by the outcome of bacteriological research, or by the heavy rate of mortality which it occasioned. Such a result, altogether unique in the history of cholera, was, I believe, largely due to the improved sanitary circumstances of England. But it is certain that if, in the cases of public water service I have been considering, the specific material which found access to the waters had been that of cholera instead of enteric fever, our cholera history for 1893 would have been the record of even greater disaster brought about in most of the cases by deliberate neglect. Even as the matter stands such instances of neglect remain a matter of reproach to our local sanitary administration."

CHOLERA.

THE latest official returns from St. Petersburg show that in the province of Volhynia there were 2497 cases of cholera and 944 deaths between Aug. 18th and 24th, and 3352 cases and 1190 deaths between Aug. 25th and 31st. In the province of Podolia 34 cases and 20 deaths occurred between Aug. 21st and 24th, and 67 cases and 25 deaths between Aug. 25th and 31st. The news of a sudden and severe outbreak of cholera in Algiers has since been contradicted by the British Consul-General at that place. It appears that there has been no such outbreak, and that Algiers is quite free from the disease.

At Constantinople, however, cases of cholera have been very frequent of late, but there are no official returns as to their number. In the neighbourhood of Broussa, also, cholera is stated to have been recently very prevalent and to have caused some anxiety to the sanitary authorities in Turkey.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6278 births and 4028 deaths were registered during the week ending Sept. 21st. The annual rate of mortality in these towns, which had been 19·9 and 19·3 per 1000 in the two preceding weeks, rose again last week to 19·8. In London the rate was 16·0 per 1000, while it averaged 22·6 in the thirty-two provincial towns. The lowest rates in these towns were 9·1 in Croydon, 12·3 in Plymouth, 14·8 in West Ham, 15·8 in Bristol, and 17·1 in Cardiff; the highest rates were 28·3 in Gateshead, 30·2 in Blackburn, 30·5 in Salford, 31·8 in Hull, and 32·9 in Sunderland. The 4028 deaths included 982 which were referred to the principal zymotic diseases, against 1071 and 991 in the two preceding weeks; of these, 689 resulted from diarrhœa, 71 from whooping-cough, 68 from "fever" (principally enteric), 65 from diphtheria, 57 from measles, 29 from scarlet fever, and 3 from small-pox. No deaths from any of these diseases were recorded in Croydon; in the other towns they caused the lowest death-rates in Huddersfield, Plymouth, Bristol, and Birkenhead, and the highest rates in Hull, Sunderland, Salford, Blackburn, and Burnley. The greatest mortality from measles occurred in Salford, Oldham, and Blackburn; from whooping-cough in Wolverhampton, Sunderland, and Gateshead; from "fever" in Swansea, Derby, Blackburn, and Sunderland; and from diarrhœa in Wolverhampton, Burnley, Preston, Hull, and Sunderland. The mortality from scarlet fever showed no marked excess in any of the large towns. The 65 deaths from diphtheria included 37 in London, 4 in West Ham, and 4 in Burnley. Two fatal cases of small-pox were registered in London and 1 in Oldham, but not one in any other of the thirty-three towns. There were 271 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, the 21st inst., against 340, 328, and 307 at the end of the three preceding weeks; 23 new cases were admitted during the week, against 36, 25, and 42 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2732, against 2512, 2600, and 2674 on the three preceding Saturdays; 344 new cases were admitted during the week, against 264, 336, and 365 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 134 and 123 in the two preceding weeks, rose again last week to 141, but were 37 below the corrected average. The causes of 44, or 1·1 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in West Ham, Cardiff, Sheffield, Newcastle-upon-Tyne, and in twelve other smaller towns; the largest proportions of uncertified deaths were registered in Birmingham, Leicester, Bradford, and Sunderland.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 17·5 and 16·9 per 1000 in the two preceding weeks, rose again to 18 5 during the week ending Sept. 21st, but was 1·3 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 10·3 in Perth and 13·1 in Paisley to 21·1 in Dundee and 23·5 in Greenock. The 534 deaths in these towns included 57 which were referred to diarrhœa, 16 to "fever," 10 to whooping-cough, 4 to scarlet fever, 3 to measles, 3 to diphtheria, and not one to small-pox. In all, 93 deaths resulted from these principal zymotic diseases, against 105 and 90 in the three preceding weeks. These 93 deaths were equal to an annual rate of 3·2 per 1000, which was 1·6 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined from 78 to 61 in the three preceding weeks, further fell to 57 last week, of which 19 occurred in Glasgow, 17 in Dundee, and 13 in Edinburgh. The deaths referred to different forms of "fever," which had been 4 and 9 in the two preceding weeks, further rose to 16 last week, and included 9 in Glasgow, 3 in Greenock, and 2 in Edinburgh. The 10 fatal cases of whooping-cough were within one of the number recorded in the preceding week, and included 6 in Glasgow and 2 in Aberdeen. The deaths from scarlet fever, which had been 8 and 4 in the two preceding weeks, were again 4 last week, of which 2 occurred in Glasgow, where the 3 fatal cases of diphtheria were also recorded. The deaths referred to diseases of the respiratory organs in these towns, which had been 56 and 52 in the two preceding weeks, rose again to 66 last week, but were 8 below the number in the corresponding week of last year. The causes of 29, or more than 5 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 22·2 and 25·4 per 1000 in the two preceding weeks, declined again to 22·1 during the week ending Sept. 21st. During the past twelve weeks of the current quarter the death-rate in the city has averaged 23·3 per 1000, the rate during the same period being 18·7 in London and 16·6 in Edinburgh. The 148 deaths registered in Dublin during the week under notice showed a decline of 22 from the number in the preceding week, and included 21 which were referred to the principal zymotic diseases, against 13 and 21 in the two preceding weeks; of these, 12 resulted from diarrhœa, 5 from "fever," 2 from scarlet fever, 1 from small-pox, 1 from whooping-cough, and not one either from measles or diphtheria. These 21 deaths were equal to an annual rate of 3·1 per 1000, the zymotic death-rate during the same period being 2·7 in London and 2·9 in Edinburgh. The fatal cases of diarrhœa, which had been 8 and 12 in the two preceding weeks, were again 12 last week. The deaths referred to different forms of "fever," which had been 1 and 4 in the two preceding weeks, further rose to 5 last week. The 2 fatal cases of scarlet fever exceeded the number recorded in any recent week. The 148 deaths in Dublin last week included 32 of infants under one year of age, and 25 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons showed a marked decline from the numbers recorded in the preceding week. Four inquest cases and 4 deaths from violence were registered; and 47, or nearly a third, of the deaths occurred in public institutions. The causes of 19, or nearly 13 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

SURGEON-COLONEL MUIR has embarked for India in the *Britannia*. Surgeon-Majors Coates, Haslett, and Weston, and Surgeon-Lieutenant Anderson have also embarked for India in the *Malabar*. Surgeon-Captain Durant has proceeded in the *Britannia*. Surgeon-Lieutenant Evans has been transferred to Gosport, and Surgeon-Lieutenant Milner to Portsmouth.

ARMY MEDICAL STAFF.

Surgeon-Lieutenant-Colonel James McGann retires on retired pay.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Lieutenant E. Hindmarsh, Bihar Light Horse, having completed three years' service is promoted to the rank of Surgeon-Captain. The services of Surgeon-Captain H. Smith, Bengal Establishment, Medical Officer, Mushkaf-Bolan State Railway, are placed at the disposal of the Home Department. Surgeon-Major C. P. Lukis, Civil Surgeon, 2nd class, Fyzabad, to officiate as Civil Surgeon, 1st class, Agra, vice Surgeon-Lieutenant-Colonel Willcocks, granted privilege leave. Surgeon-Major J. F. Tuohy, Civil Surgeon, is transferred from Saharanpur to Bareilly. Surgeon-Captain H. W. Elphick, Civil Surgeon, from Muzaffarnagar to Saharanpur, and to hold Visiting Medical Charge of the Muzaffarnagar district in addition to his other duties.

NAVAL MEDICAL SERVICE.

Surgeon R. F. Bate to the *Briton*.

ARMY MEDICAL RESERVE OF OFFICERS.

The promotion to the rank of Surgeon-Major of Surgeon-Captain George Middlemiss, M.D., is antedated to Oct. 30th, 1894. The undermentioned Surgeon-Captains, 1st Banff Volunteer Artillery (Southern Division Royal Artillery), to be Surgeon-Majors:—William Fergusson, M.D., and William Lemmon Stewart, M.D. The undermentioned officers to be Surgeon-Captains:—Surgeon-Captain Francis William Grant, M.D., 1st Banff Volunteer Artillery (Southern Division Royal Artillery); Surgeon-Lieutenant William Beddie, M.B., 1st Banff Volunteer Artillery (Southern Division, Royal Artillery); and Surgeon-Captain Joseph Adams, M.B., 1st Volunteer Battalion the Prince of Wales's Volunteers (South Lancashire Regiment). Surgeon-Lieutenant Alexander Barclay Lyon, M.B., 1st Banff Volunteer Artillery (Southern Division, Royal Artillery), to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Artillery: 1st Cheshire and Carnarvonshire: Surgeon-Lieutenant R. L. Jones to be Surgeon-Captain. 3rd Durham (Western Division, Royal Artillery): Surgeon-Lieutenant F. W. Sinclair, M.B., to be Surgeon-Captain. *Rifle:* 3rd Volunteer Battalion the King's (Liverpool Regiment): Surgeon-Lieutenant W. J. M. Barry resigns his commission. *Memoranda:* 1st Argyll and Bute Volunteer Artillery: The undermentioned officers retire:—Honorary Assistant-Surgeon J. Mackenzie and Honorary Assistant-Surgeon J. MacGowan, M.D. 1st Volunteer Battalion the Royal Scots Fusiliers: Surgeon-Major R. Munro, M.D., retires, with permission to retain his rank, and to continue to wear the uniform of the Battalion on his retirement.

INDIAN SANITARY AND MEDICAL REPORTS.

The Army Sanitary Commission, in a recently published memorandum on the report of the Sanitary Commissioner with the Government of India for 1893, calls attention to the voluminous statistical tables embodied in these reports, and states that the elaborateness of detail with which they are prepared, although evidencing great care and industry on the part of the compilers, is nevertheless often a source of embarrassment to those desirous of ascertaining the recorded facts and of obtaining a history of the principal events of the year. The Commission makes numerous suggestions for curtailing and remodelling the tabular portion of the reports. Some years ago we adverted to this subject. Indian reports and Blue-books bristle with statistics and figures which tend to hide rather than elucidate and accentuate the points of real interest and requiring attention. Now that arrangements have been made by which the three Presidential armies have been replaced by four army corps the time seems to have come for reconsidering this matter and for seeing whether it cannot be put upon another and improved basis. The geographical areas into which the European and native armies have been grouped are to a large extent arbitrary and have little or no bearing on the study of epidemic disease. The medical history of corps and the sanitary and medical history of important stations should be recorded for several more or less obvious reasons. As the Sanitary Commission urges, the question as to the order in which stations could be best occupied by European regiments during their tour of Indian service might, for example, be settled on reliable data. We should like to hear, moreover, that something like a handbook or guide embodying all the more important sanitary, medical, topographical, and local points connected with every big military station had been compiled and was available for reference. Military and medical officers at the various commands or large military stations should have something of the sort to which they could refer and from which they could obtain all necessary information about the climate, the geographical features, water-supply, diseases, &c., of any given district or station.

ARMY MEDICAL SCHOOL, NETLEY.

The seventy-first session of the Army Medical School will commence on Wednesday, Oct. 2nd. The session will be attended by twenty-eight surgeons on probation, ten for admission to the Army Medical Staff and eighteen for admission to the Indian Medical Service. The following are the lists of those about to join the school:—

ARMY MEDICAL STAFF.

F. S. Brereton.	M. L. M. Vaudin.
J. C. B. Statham.	W. A. Ward.
P. J. Probyn.	E. G. Forrest.
R. M. C. H. Cooper.	A. W. Hooper.
A. H. Waring.	E. C. Hayes.

INDIAN MEDICAL SERVICE.

W. W. Clemesha.	K. V. Kirkday.
A. W. R. Cochrane.	E. R. Rost.
V. E. H. Lindesay.	C. B. Harrison.
R. P. Wilson.	W. J. Niblock.
N. R. J. Rainier.	E. L. E. F. Payne.
E. L. Perry.	N. P. O'G. Lalor.
J. A. Black.	J. C. Robertson.
J. H. Symons.	C. D. Dawes.
C. R. Bakhla.	M. B. Pinehard.

The *Broad Arrow* says: "Enteric fever is causing havoc among our young officers at Bangalore. The recent death of Second Lieutenant MacTier, of the Dorsetshire Regiment, at the Station Hospital, where he was under treatment, brings the mortality up to three from this disease, while five deaths in all have occurred among the subalterns of the garrison. All officers who have been quartered at Bangalore are well aware that the drinking water for the cantonment is derived from a tank supplied by an open channel which passes through a native bazaar, kept clean by sweepers. Forming part of the wall of the supply channel is the main sewer from the same area. This sewer is so ingeniously arranged that when overcharged with storm water relief is obtained by discharge into the water-supply channel, and thus into the tank. These facts were laid before the Indian Medical Congress by the Sanitary Commissioner, Madras, in an instructive address on sanitation in India."

THE VOLUNTEER OFFICERS' DECORATION.

The Queen has conferred the Volunteer Officers' Decoration upon the undermentioned officers of the Volunteer Force:—*North-Eastern District: Artillery:* 2nd West Riding of Yorkshire (Western Division, Royal Artillery): Surgeon-Lieutenant-Colonel Isaac Mossop. 1st Volunteer Battalion the Duke of Wellington's (West Riding Regiment): Surgeon-Lieutenant-Colonel Thomas Michael Dolan. 1st Volunteer Battalion the Sherwood Foresters (Derbyshire Regiment): Surgeon-Lieutenant Thomas Johnston, retired. *Western District: Rifle:* 1st (Brecknockshire) Volunteer Battalion the South Wales Borderers: Surgeon-Lieutenant-Colonel Philip Edward Hill.

CHRIST'S HOSPITAL.—Prizes of £50, £40, and £30 respectively are offered for the three best essays on the condition of Christ's Hospital and the means of surmounting its difficulties. Intending competitors should apply to Sir J. Causton and Sons, 9, Eastcheap, E.C., for a copy of "The Christ's Hospital Controversy" and for further particulars and suggestions. The essays must be delivered on or before Dec. 31st, 1895.

Correspondence.

"Audi alteram partem."

THE THROAT HOSPITAL, GOLDEN SQUARE.

To the Editors of THE LANCET.

SIRS,—While we thought it expedient to announce publicly the severance of our connexion with the Throat Hospital, we did not think it necessary in the interests of the institution to state at the time our reasons for so doing. As, however, others think differently, we now ask you to publish the following statement. We are, Sirs, yours obediently,

SUTHERLAND,
R. COURTENAY WELCH,
GREVILLE MACDONALD.

Sept. 25th, 1895.

STATEMENT.

At the annual general meeting of the governors and subscribers of the Throat Hospital held on April 10th last, after Mr. Courtenay Welch and two others of the retiring members had been unanimously re-elected, four other gentlemen (Dr. Norris Wolfenden, a former member of the honorary medical staff of the hospital, Major Probyn, Mr. Allom, and Mr. Osborne) were, after opposition, elected to serve on the Committee of Management. A few days later it was discovered that among those who had voted in support of these gentlemen were several persons who, in order to obtain a colourable qualification to vote under By-law 16 ("No annual subscriber shall be entitled to vote until after the payment of his subscription for the second year"), had, a few days before the meeting, paid to the secretary a subscription with the request that one moiety should be entered as a subscription for 1894 and the remainder as for 1895, one of the four gentlemen thus elected having himself in this manner obtained his qualification to vote. Although some of these payments were made just before the monthly committee meeting of April 2nd, the secretary made no mention to the committee of this unusual procedure, nor did he at the annual general meeting, when the qualification of one voter was challenged, give any hint that anything irregular had taken place. At the next committee meeting, held on May 7th, Dr. MacDonald proposed and Mr. Welch seconded a resolution to the effect that a special general meeting of the governors and subscribers should be called to reconsider the opposed resolutions passed at the annual meeting. When this proposal was rejected, and the committee thus refused to allow the question to be reopened and the facts laid before the subscribers, Dr. MacDonald and Mr. Welch at once resigned. The Duke of Sutherland, at the earnest request of Mr. G. H. Pember, the new chairman, and of Dr. MacDonald, who, acting independently of each other, pointed out the irreparable injury which his Grace's resignation would inflict upon the hospital, consented to defer any definite step until it could be ascertained whether the four gentlemen, the validity of whose election had been called in question, would voluntarily retire. A deputation from the committee subsequently waited upon the president, but as the arrangement he had suggested was not carried out, he had no alternative but to resign.

"THE PICRIC ACID TEST FOR SUGAR IN THE URINE."

To the Editors of THE LANCET.

SIRS,—Having been much away from home during the last few weeks I have only just now seen Professor Campbell Black's letter on the above subject in your issue of Aug. 24th. The Professor states that the addition of picric acid and potash to urine containing sugar causes a reddish colouration in the cold, and that the same results occur in perfectly normal urine, the reaction being more marked in urine containing an abundance of uric acid. The facts are as thus stated, but I beg permission to give the explanation which your correspondent omits to give. The reddish colouration with picric acid and potash *at the ordinary temperature* in urine, whether normal or saccharine, is due entirely to kreatinin, the strongest solution of glucose having, when cold, no reducing action on picric acid and potash until after an interval of at least an hour. The more marked reaction in urine with an excess of uric acid is due to the associated excess of kreatinin, and not to uric acid, which has no reducing action upon picric acid, although it has upon Fehling's solution.

The Professor's statement that when urine containing sugar to which picric acid and potash have been added is boiled the fluid assumes "a claret colour, which passes on cooling to a deep port wine colour" suggests the question, How often has he used the test, the action of which he so inaccurately describes?

A first year's student may be taught in a quarter of an hour the strikingly different results of boiling for a minute a normal and a saccharine specimen of urine to which the picric acid test has been added. The former assumes a bright red colour, while urine containing sugar becomes so black that not a gleam of light appears through the middle of the test-tube. Has the learned Professor ever met with a sample of port wine as dark as this? If Professor Campbell Black had done me the honour to read carefully two papers of mine which have been published in THE LANCET, one on "Some Common Sources of Error in Testing for Sugar in the Urine,"[1] and the other on "The Absence of Sugar from Normal Urine proved by a New and Simple Method,"[2] he surely would not have asserted that the picric acid test "is eminently fallacious and should be discarded for either qualitative or quantitative analysis of sugar in the urine." In opposition to this condemnatory assertion I venture to predict that at no distant period every competent observer will acknowledge that as a qualitative and quantitative test for both albumin and sugar in the urine picric acid is the most valuable test agent that modern science has placed in the hands of the profession.

I am, Sirs, yours faithfully,

Savile-row, Sept. 23rd, 1895. GEORGE JOHNSON.

"PRESYSTOLIC APEX MURMURS."

To the Editors of THE LANCET

SIRS,—Having read with pleasure and instruction Dr. A. G. Phear's excellent paper on Presystolic Apex Murmur without Mitral Stenosis in THE LANCET of Sept. 21st, and appreciating his very cogent argument in favour of the theory he advances in explanation of the bruit under these circumstances, I desire to offer a remark upon one point to which he makes reference. The two factors, in his opinion, productive of the presystolic bruit are narrowing of the mitral orifice from any cause and the occurrence of sufficiently forcible auricular contraction to generate a fluid vein. Were we to accept this second factor as the efficient cause of the murmur the condition might more precisely be termed auricular systolic murmur—a term which, if my memory does not mislead me, has already been applied to it.

It has long appeared to me, however (and so long ago as 1878 I published the view), that the most potent cause of the mitral diastolic bruit, after the organic narrowing, actual or potential, necessary, is the condition of the left ventricle and the aspirative force of that cavity. As Dr. Phear remarks, the so-called presystolic bruit may occupy varying portions of the diastolic interval. It may in time be possible to associate more exactly the bruit of a certain phase of that interval with a special organic condition, but all we can at present say is that the bruit is not systolic, and is therefore diastolic, while a frequently associated phenomenon is the time, situation, and character of the thrill. The latter frequently so exactly corresponds in all its phases to the audible phenomenon that one may by palpation arrive at a diagnosis without the aid of the stethoscope. The conditions, moreover, with which the non-stenotic bruit in question is usually associated—namely, hypertrophy and dilatation of the left ventricle from aortic valvular disease or adherent pericardium—appear to me to strengthen my contention that it is the aspirative power of that cavity rather than the propulsive power of auricular systole which is operative in the production of at least the greater part of the mitral diastolic bruit. The fugitive character of that sound, moreover, seems to me to depend rather upon a variation in the force of valvular contraction, and its consequence ventricular diastole, than upon fluctuations in the power of auricular contraction.

A valuable aid to the diagnosis of apex diastolic bruit dependent upon non-stenotic conditions is, in my opinion, the too much discarded sphygmograph.

I am, Sirs, yours faithfully,

ALEXANDER MORISON, M.D.

Upper Berkeley-street, W., Sept. 23rd, 1895.

To the Editors of THE LANCET.

SIRS,—Referring to the subject of presystolic apex murmurs, can there be a thrill without a corresponding murmur? In Dr. A. G. Phear's interesting paper on Presystolic Apex Murmur without Mitral Stenosis I notice the record in Case 2 of the occurrence on one occasion of a thrill of presystolic rhythm confined to the region of the apex, unaccompanied by a corresponding presystolic murmur.

[1] THE LANCET, July 7th, 1894.
[2] THE LANCET, Jan. 12th, 1895.

The observation raises a point important clinically. I suppose the prevailing view is that, whilst a murmur need not be felt as a thrill, a thrill will always be heard as a murmur. Is this prevailing view incorrect? So far as my own experience goes I should say that wherever I have felt a thrill I have heard a corresponding murmur; but my impression is that on more than one occasion I have felt some difficulty in assuring myself that the thrill felt and the murmur heard coincided accurately in point of time. Physically regarded, it is, I suppose, quite possible to conceive that the vibrations or ripples should be so coarse and infrequent as to be palpable and not audible; but in practical medicine is this the case? If it be the case the hand should, I think, take cognisance of the thrill as special in character—special by reason of its extreme coarse or undulatory character.

I am, Sirs, yours truly,

HARRINGTON SAINSBURY.

Welbeck-street, W., Sept. 23rd, 1895.

To the Editors of THE LANCET.

SIRS,—Dr. Phear, in his paper upon the occurrence of a presystolic murmur without mitral stenosis, mentions the presence of thickened and shortened chordæ tendineæ in his cases, and suggests that, although the mitral orifice was of normal size, a virtual stenosis may have been produced during diastole by the reaction of these shortened cords upon the edges of the mitral flaps. Although mitral stenosis may generally be said to be as much a disease of the chordæ tendineæ as of the flaps of the mitral valve, cases may undoubtedly occur in which some thickening and shortening of the chordæ tendineæ exist without any associated narrowing of the mitral orifice. Only to-day I made a post-mortem examination upon such a case. While, however, I believe in the possibility of such a lesion I do not think that this shortening of the chordæ tendineæ can easily produce the virtual narrowing of the mitral orifice that Dr. Phear supposes may be present during diastole. When the edges of the mitral flaps remain quite flexible it seems reasonable to conclude that the orifice will maintain its full circumference while blood is flowing from the auricle to the ventricle, since during the time the flow continues the pressure upon the auricular surface of the flaps must be greater than upon the ventricular. Dr. Phear states that artificial traction upon the musculi papillares will demonstrate how the flaps can be drawn down and the orifice narrowed. It is doubtless true that the mitral orifice can be narrowed by such traction, but the excess of tension is upon the ventricular edges of the flaps in such a case, and before this state of tension could be reached in the ventricle during diastole it seems to me that the flow of blood from the auricle would cease. Allowing, however, that such a condition could be present, it could only occur when the ventricle had become filled or nearly filled with blood—in other words, the virtual stenosis would occur towards the end of diastole and the murmur it occasioned be presystolic in time. But in one of Dr. Phear's cases the murmur was sometimes early diastolic in time. This murmur could hardly have been produced by a virtual stenosis of the character he suggests. In closing I may say that since reading Dr. Phear's paper I have examined the mitral orifice of the heart from the case of presystolic murmur occurring with disease of the aortic orifice recorded by me in THE LANCET. There can be no suspicion of shortened chordæ tendineæ being the cause of the murmur in that case. Not only do I not believe that the *veine fluide* theory will explain anomalous presystolic murmurs, but the true presystolic murmur is often of such peculiar character and so different from other murmurs that it seems possible that its true explanation has yet to be discovered.

I am, Sirs, yours truly,

Pembroke-road, Clifton, Sept. 24th, 1895. THEODORE FISHER.

"HOSPITAL ABUSE AT BRIGHTON."

To the Editors of THE LANCET.

SIRS,—In your issue of Sept. 21st you quote from a letter of Dr. Waring with respect to hospital abuse at Brighton. Whilst fully endorsing your view as to the kindly spirit in which the letter is written, yet as regards the most important charity mentioned there are additional facts which may modify the judgment of many. 1. The Sussex County Hospital received during the first six months of this year 35·8 per cent. of its in-patients and 21 per cent. of its out-patients from the county, as opposed to Brighton and Hove. Hence the patients are drawn from a population of considerably over 150,000. 2. In the annual report for the year ending 1894 the following paragraph occurs: "A searching scrutiny was made this year by a subcommittee, which showed that 96 per cent. of the cases (out-patients) were entirely fit and proper subjects for gratuitous treatment, and though in the remaining 4 per cent. sufficient information could not be obtained, it was thought that even in these cases, were closer scrutiny possible, it might be shown that several could be received without any abuse of the charity." May I suggest that the primary cause of hospital abuse is the carelessness with which subscribers give their tickets.

I am, Sirs, yours faithfully,

ADOLPHUS J. RICHARDSON,
Assistant Physician to the Sussex County Hospital.

St. John's-terrace, West Brighton,
Sept. 24th, 1895.

"THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK."

To the Editors of THE LANCET.

SIRS,—The note which you inserted immediately after my letter[1] calls attention to a fact with which I have long been acquainted and of which I venture to think a complete explanation can be given. I must, however, premise my remarks by calling attention to the fact that it is an error to suppose that I regarded death from electric shock as "simply a violent disturbance of the normal magnetic lines of flow through the body," although such disturbance must occur. What I said was "that it is impossible to separate the physics of the cause of death from electric shock from the physics which are continuously operating to maintain the phenomena of life." I then proceeded to show that the passage of the arterial blood over the nerves and other conductors of impressions, in proportion to the oxyhæmoglobin present, which is a highly magnetic substance, gives rise to currents of energy through the nerves which from their effects appear to be of the same character as the currents of energy obtained by passing an electric current through a nerve or muscle. This conclusion is in accordance with the generally received opinion that electricity and magnetism are manifestations of one and the same force. Thus, in the case of death from electric shock and in the process of life under normal conditions the active cause of the phenomena is found to be the same, the different result in each case being due to the different degree in which the force was present. My remarks about the magnetic lines of force through the body due to the magnetism of the earth do not materially affect this argument. They were intended to elucidate one of the causes of the magnetic energy possessed by the corpuscles of the arterial blood. Before passing on I may mention that I did not wish to imply that an electric charge might not enter the body at any point and in doing so by its disruptive effects be productive of such lesions as would necessarily prove fatal. My observations were directed more especially to showing the cause of the phenomena recorded by Dr. A. M. Bleile.

I now come to the explanation of the facts brought forward in your note. You say that "if death from electric shock were simply a violent disturbance of the normal magnetic lines of flow through the body, we should at least expect marked physiological effects in animals placed in strong magnetic fields of large electro-magnets, for under these conditions the lines of magnetic flow through the body are completely altered. No such effects, however, are manifest, the man or animal placed under such conditions being completely unconscious that anything abnormal is going on." I must in the first place direct attention to some well-known facts of magnetism and electricity. 1. Every form of matter has what may be called its own specific capacity for magnetic energy. In other words, every form of matter, when suspended in a magnetic field, assumes a definite axial inclination with reference to the poles of the magnet, which is peculiar to itself; and in accordance with its axial inclination any particular substance is termed magnetic or diamagnetic. 2. This magnetic capacity is most apparent in soft iron. In iron, therefore, we shall find the clearest

[1] THE LANCET, Sept. 14th, 1895.

Digitized by Google

example of the effect produced upon a body by placing it in a magnetic field.

Now a bar of iron when brought under the influence of an electro-magnet becomes itself a magnet, possessing north and south poles and manifesting all the phenomena of magnetism. This manifestation of magnetism is generally believed to be due to a particular arrangement of the molecules of the bar of iron effected by the power of the magnet—an arrangement in which the axes and similar poles of the molecules are made to point in the same direction. In the case of steel it is thought that the molecules, after being once arranged with their poles all pointing north and south, retain that position owing to the material condition of the bar. Consequently, when soft iron, steel, or, indeed, any form of matter—magnetic or diamagnetic—is subjected to the influence of a magnet, the power of the magnet so far is of little consequence, and the only result that can occur as a direct effect of the magnetism is a change in the direction of the molecules, determined by their own individual character and in accordance with the force which is acting upon them. But, further, it is probable that the diamagnetic molecules in the living body are continuously rotating upon a definite axis, the axis of rotation in every case being determined by the relation which each form of matter has to the magnetic force. I venture to hold this opinion because a sphere of copper (which is one of the most diamagnetic forms of matter) will rotate upon its axis when suspended in a magnetic field;[2] and I have myself ascertained from experiment that the direction of the rotation depends upon the position of the magnetic poles in relation to the sphere, whilst the rapidity of the rotation is in proportion to the intensity of the magnetic field. From this fact in the case of copper I think we may not unjustly infer that other forms of diamagnetic matter, if subjected to the same conditions, would behave in a similar way; and if so, I think that we have in this fact a cause for those rotations under which inanimate matter is converted into living cells in the animal body through centripetal and centrifugal force, as described by Dr. Lionel Beale,[3] whilst the selective influence which each form of matter, through its specific constitution and magnetic capacity, exercises would determine the character of the matter which each molecular germ withdraws from the nutrient plasma flowing over it. The character of the matter abstracted being thus determined by the polarity of the matter composing the germ, the importation of other matter of any kind into the blood corpuscles or into any tissue of the body, which is inconsistent with perfect health, would be productive of modifications of motion and of function, the natural tendency of which would be to produce disorder, disease, and death. In fact, this theory says that all disorder or disease is as much the outcome of the introduction of material particles into the system which should be foreign to it as the natural body is the result of the particular mode in which certain forms of matter under the influence of an all-pervading force are converted into it. I cannot, therefore, perceive that there would be any modification of natural phenomena under the conditions to which you refer, other than those which are consistent with the maintenance of the phenomena of life in a state of perfect health. In fact, it is clear that, under the known relations which exist between matter and the magnetic force, the only influence which magnetism can exercise upon the living body is to render the polarity of every atom engaged in the maintenance of life more marked, and therefore more capable of maintaining those phenomena which are naturally evolved during life by the material elements. And if this be so, there is no reason why an animal or person placed in the field of a strong electro-magnet should be conscious of the changed conditions; for as we are not conscious of natural and healthy bodily processes, such as the passage of the blood through the arteries and veins, the digestion of food, and the formation of tissue, so are we conscious of influence from an external source, such as the electro-magnet in question, only to the extent to which natural functions of the body are affected or modified thereby. But when the body is subjected to the action of the electric force a totally different condition of things exists, and the resulting phenomena must vary with the extent of the shock, whether it be in the form of static or dynamic charge. And this leads me on to reply very briefly to the note of Dr. McClure which appeared in the last issue of THE LANCET.

In the first place I would remark that in discussing the nature of the conductive or the dielectric properties of matter a due recognition of the broad principle that all bodies are conductors of electricity will tend to render this rather abstruse subject somewhat more easy of comprehension. It is a fact that every form of matter has its own specific power of conducting a current; and some bodies transmit the force with such great resistance that Faraday gave them the name of dielectrics, for they appear to convey the force from molecule to molecule more by induction than by conduction. In these substances, therefore, in proportion to the greater resistance which they oppose to the passage of the current, the presence and force of the electric energy will be most clearly manifested by the production of heat and disruptive effects. In the animal body the blood is unquestionably the best conductor—i.e., it is the substance which most strongly attracts the charge of electricity and transmits it to the earth. In this respect it performs the function of an ordinary lightning conductor. But the other tissues, in proportion to their resistance, may be classified as dielectrics, for they tend to throw the energy outwards more or less at right angles to the direction of the current, and they are in such a degree liable to suffer from disruptive effects. Whilst thanking Dr. McClure for his criticism of my paper, I would add that I quite concur with him in his remark that in the proper understanding of these phenomena lies the solution of many physiological problems. But I go further than this, and express my conviction that this magneto-electric theory of life involves the principle by which almost *all* vital phenomena may be explained.

I am, Sirs, yours faithfully,

Reading, Sept. 21st, 1895. RICHARD C. SHEPPLE.

[2] I exhibited this experiment at a conversazione of the Royal Society in May, 1857, and subsequently before the Physical Society of London. Vide Protoplasm: or Matter and Life, by Lionel S. Beale, F.R.S., 2nd edition, p. 277, &c.

"DIPHTHERIA IN LONDON."

To the Editors of THE LANCET.

SIRS,—I should like to say a word with reference to the annotation under the above heading which appeared in THE LANCET of Sept. 21st. During some investigations into an outbreak of scarlet fever I came upon some conditions and usages of ordinary elementary school life which appeared to me to be likely to have a distinct, and apparently previously unrecognised, influence on the spread of such diseases as scarlet fever and diphtheria. I found that the slates and pencils were used by the children quite indiscriminately, and that when it was necessary to rub out sums, copies, &c. it was done by licking with the tongue and using saliva; and, moreover, that the slates were never washed. Taking into consideration the fact that the naso-pharyngeal secretion in scarlet fever and diphtheria carries infection long after the patient is apparently convalescent, it is easy to understand that the circumstances above mentioned would have a potent influence in spreading these diseases.

I am, Sirs, yours faithfully,

Halesowen, Sept. 21st, 1895. T. BRETT-YOUNG.

"THE MANCHESTER MEDICAL CRICKET CLUB."

To the Editors of THE LANCET.

SIRS,—There is a slight inaccuracy in the article on the above subject in the current number of THE LANCET. This has been the fourth season since the club was constituted, and for two seasons previously a few matches were played, which led to the formation of the club.

I am, Sirs, yours faithfully,

G. H. BROADBENT.

authority of the figures I have drawn from the
kingdom Postal and Telegraph Service Benevolent
reports with reference to the health and mortality
graph clerks. Suffice it to say that after thirteen

service in the telegraph department I am convinced that the members of the society are a representative body. It will be for the statistics of the department to prove the accuracy or otherwise of my confident belief in the typical value of my figures. In the meantime it would, however, be well to draw your attention to the inaccuracy of your information concerning the "declaration of health" rule. This rule was certainly in force nine years ago when I became a member of the society, and to the best of my belief its origin was coeval with the society's. The point in my evidence which struck me as being most conclusive was that relating to the annual average sick absence. This, I believe, I proved by comparison to be greatly in excess of that of the general populace, and if consideration is had to the facts of initial health, low age, and free medical attendance it seems to me to point conclusively to some serious conditions prejudicial to health which are obviously and continuously undermining the constitution of the men. Thanking you for the space already allotted to this subject,

I am, Sirs, yours faithfully,

West Brompton, Sept. 18th, 1895. CHARLES H. GARLAND.

"COUNTRY PRACTITIONERS AND LOCUM-TENENTS."

To the Editors of THE LANCET.

SIRS,—I can sympathise with all your correspondent states in his letter to THE LANCET on the 31st ult. concerning locum-tenents. When practising at Storey's Gate, Westminster, some ten years since I employed some four or five of these gentlemen (at three guineas per week, with travelling expenses), and I am sorry to say that I was singularly unfortunate with each of them. Without entering fully into details I found one and all lazy, neglectful to the patients under their care, careless in their work, and generally given to the charms of Bacchus. One man robbed me of an account of about £8 which he received from a patient on my behalf, and bolted, after being in charge but a few days, leaving me to settle a bill at a hotel for bottled ale, spirits, and other luxuries, my holiday being necessarily abruptly brought to an end by these and other delinquencies of this worthless man, whom I have not seen since. For more than five years I adopted the work of a locum-tenent, and in *no* house was I so unlucky as to meet with "an untidy woman to come in occasionally during the day to see if I required anything," where the kitchen did duty for the consulting and sitting rooms, and the scullery for the kitchen, wherein the various meals also were prepared, as stated by "Locum-tenent" in THE LANCET of Sept. 14th. On the contrary, I found each of the residences well appointed, the board all that one could desire, the stipend liberal—my fees ranged from three to five guineas weekly, with railway and cab fares—and the arrangements for a stranger excellently planned. Indeed, I always felt "in clover." On retiring from this employment in 1877 I had a first-class connexion, representing my numerous principals time after time, and I had constant occupation, which I now and ever shall remember with very great pleasure.

I am, Sirs, yours faithfully,

J. FFRENCH BLAKE.

High-street, Putney, S.W., Sept. 14th, 1895.

GUARDIANS AND MEDICAL OFFICERS.

To the Editors of THE LANCET.

SIRS,—I shall feel obliged if you will kindly publish the following case in your correspondence columns and give me your opinion on the same, and I also hope I may be favoured with an expression of opinion by some Poor-law medical officers. The medical officer of a certain union receives an order from the relieving officer to attend a young man. He finds him suffering from influenza and sore-throat with great difficulty of swallowing. On Aug. 1st he gave the usual recommendation form for one pint of port wine; and on Aug. 5th another for two pounds of beef for beef-tea. After this an abscess formed at the root of one of the molar teeth and the jaws became fixed; with great difficulty the tooth was extracted, but the jaws remained fixed for many days. On the 18th a further supply of two pounds of beef is advised, and on the 23rd, he being obliged to live entirely on suction, a further supply of two pounds of beef and also two pounds of linseed meal for poulticing. The relieving officer allowed the linseed meal, but delayed the beef, on the ground, I believe, order of the 18th was not presented until the 20th an too soon to grant more: it was given the following 24th. The 24th was board day, and I attended as g and called attention to the fact. The same thi occurred before in the case of an old woman with b pneumonia for whom two pounds of beef and half a brandy were recommended. The beef was granted brandy refused because the relieving officer said the buy that themselves in the village. I must no that for many years I was medical officer union. Having resigned and having been elected gua supported the medical officer. I contended that i the province of the relieving officer to decide on the of beef required. I find an opinion expressed that the r officer was acting quite within his rights in refusi thought fit, and as this may be prejudicial in the want to get an opinion from THE LANCET. I know a officer can only recommend, but when once the prin relief is established as necessary the medical office judge of the quantity required and not the relieving As the law now stands it appears that a relieving off give an order to the medical officer and compel his ance, and at the same time control his medical extras I think, should be altered, and any recommendation medical officer should be carried out at once. The be reported at the next board meeting and the medica called upon to explain his action. I am bound t believe I had the sympathy of the board and of a of them, but as at least one influential member thinks I have not made out a case, and as his opin influence future cases, I am desirous of a good public

I am, Sirs, yours faithfully,

Sept. 17th, 1895. A GUAR

*** It ought to be widely known that a relievin has *no* absolute discretion in dealing with a case of necessity, and, therefore, if he refuses to carry out the recommendations for food and stimulants and the dies he can be held responsible—*vide* the case of Jeslin, in which Mr. Justice Hawkins made some ver and appropriate remarks on the conduct of the d relieving officer, whose conviction was confirmed. U present power of the relieving officer is curtailed ir to his carrying out the orders of the medical officer i right that the medical officer, on refusal of his o medical relief being given, should personally att next meeting of the board and lay his case before it public exposure would do much to remedy the unsatisfactory state of affairs.—ED. L.

THE DEARTH OF MAGISTRATES

To the Editors of THE LANCET.

SIRS,—Much inconvenience is caused in our neighb owing to the fewness of the local magistrates. To a tion of nearly 8000 we have three "resident" magi It sounds like a joke, but only one of the three reside place, and he is often away ill. Another lives abou and a half away, and the third lives in London, nea miles away. The last-named comes down near Saturday till Monday when his house is not let, and regular visit in addition for the shooting. It is imagine the result when it is necessary to ce lunatic. On one occasion I had a raving maniac with the police from morning till evening, when we the London magistrate on his way from the trai another occasion no magistrate could be obtained patient could not be certified at all. The last Gov was very busy in converting labouring men into magis why should this one not do something to remedy th evil by appointing men of education—such as prof men, gentlemen farmers, &c.—without regard to influence!

"ROUGH NOTES ON REMEDIES."

To the Editors of THE LANCET.

SIRS,—I am extremely glad to see some more "Rough Notes" by Dr. Murray of Newcastle-on-

Digitized by Google

THE LANCET of Sept. 21st, and I am sure that we country practitioners value a practical paper such as he occasionally (I wish it were oftener) sends to THE LANCET far more than all the many learned and scientific papers so frequently to be read in its columns. Unless one has opportunities of keeping up one's scientific knowledge these latter are frequently "out of our depth," and it is the shorter and more practical articles that we instinctively turn to and read; for in our multifarious duties we have no time to speculate and theorise in matters of diagnosis &c., but must have our remedies ready in our minds, and they must be of a practical nature or our patients cannot understand them. I hope others of your readers will be induced to give us some notes on treatment in a short and concise form from time to time.

I am, Sirs, yours faithfully,

Sept. 21st, 1895. M.D.

THE FIFTH INTERNATIONAL CONGRESS OF OTOLOGY.

(FROM A SPECIAL CORRESPONDENT.)

Introductory.

AURAL MEDICINE is one of the very youngest of the "specialties." Its tardy appearance on the professional field is, however, quite explicable; for one thing, the exceeding complexity of the organ of hearing, anatomically, physiologically, and pathologically considered, imposes greater difficulties on its investigators than any other of the "gateways of knowledge." It was not till late in the seventeenth century that we gained a first glimpse into its anatomy, Guichard du Verneu, demonstrator of anatomy at the Jardin des Plantes, having been the first to put the structure and mechanism of the ear in an intelligible light.[1] After this came Valsalva of Bologna, whose masterwork[2] marks a fresh advance in our knowledge of the anatomy, the physiology, and the pathology of the organ. But neither French nor Italian physicians improved much on the traditional treatment of injuries to the ear, the invention of the ear-mirror by Fabry and of an artificial ear-drum (made of a piece of sow's bladder stretched over a short tube) by Marcus Banzer remaining, both before and after them, the sole contribution to the remedial armoury. The first step towards a more accurate knowledge of the ailments of the inner ear was the invention of the catheterism of the Eustachian tube by Guzot, postmaster at Versailles, in 1724, and by Archibald Cleland in 1741, the former of whom introduced the instrument through the mouth, while the latter, to whom we also owe the artificial illumination of the tympanum, passed it through the nose. Notable progress in aural medicine, however, really begins with Jean Marie Gaspard Itard of Paris. He initiated the use of the catheterism of the ear-trumpet for the diagnosis and treatment of diseases of the tympanum, and this was utilised and followed up by Leon Delean, the inventor of the air-douche—a physician, by the way, who did much for the education of deaf-mutes. Later workers in the field were Karl Joseph Beck of Freiburg (1804–1844) and Wilhelm Kramer of Berlin (1801–1875), the founder of auscultation of the middle ear. The more recent work of Wilde, Toynbee, Tröltsch, De Rossi, and others belongs to contemporary history—familiar to the members of the last and greatest, because most systematic, association for the promotion of aural medicine, the International Congress of Otology. Of those members few have won a more honourable record than the comparatively young president of the fifth Congress, about to assemble in Florence, Dr. Vittorio Grazzi. Born at Sinalunga, near Siena, he entered on the study of medicine in the Sienese school, and obtained with unusual distinction his "Diploma di Laurea" (graduation in medicine) on July 22nd, 1872. His subsequent career has been one long march of honourable qualifications, certified by testimonials from masters in the science of the healing art such as Pacini, Paoli, Morelli, Ghinozzi, and others among his compatriots, and from Peter, Fauval, Ladreit de la Charrière, Gellè, Miot, Barker, Morell Mackenzie, and others abroad. In 1884 Dr. Grazzi obtained by examination the "Decreto della Libera Docenza in Otologia" in the Roman school, and thereafter received authorisation to give a free course of lectures in aural medicine in the Istituto di Studi Superiori at Florence. At the instance of Dr. Guido Baccelli, now Minister of Public Instruction, His Majesty King Humbert conferred on him the honour of Cavaliere of the Crown of Italy in 1884. Since then he has served on many commissions, educational and professional, and was a prominent member of the Organising Committee of the Otological Section of the Eleventh International Congress held in Rome in the spring of 1893. A more recent distinction is his appointment as Professor of Oto-Rhino-Laryngologia in the University of Pisa, a post he fills with yearly enhanced acceptance, and which, from being an occasional, has under his auspices become a permanent adjunct to the medical curriculum of that seat of learning.

Professor Grazzi's connexion with the Continental and the British School of Medicine is of long standing. In February, 1875, he obtained by examination the "Posti di Studio Biringacci" (travelling fellowship) of Siena, and also by examination the "Alunnato Jacchini" (a similar foundation) of Florence, enabling him to spend eight years at the leading cliniques of Europe. In the two scholastic years 1877–78 and 1878–79, during which Dr. Grazzi resided in Paris and London for the special study of otology and rhinolaryngology, he enjoyed an extraordinary money-grant from the Ministry of Public Instruction. The fruits of this comprehensive and accurate course of study he has given to the world in many publications, principally in his capacity as director of the "Bollettino delle Malattie dell' Orecchio, della Gola, e del Naso," his able and impartial editing of which obtained him gratifying recognition at more than one Congress, national and international. His "Manuale Completo d'Otologia: compilato per i Medici-Chirurghi e per gli Studenti" enjoys exceptional popularity in the Italian schools. He has also translated the American works on "Aural Diseases" by Dr. Buck and Dr. Lefferts of New York, and has long been the quasi-official *internuntius* between the Italian and the English-speaking world in the field of otology.

The general business of the Congress will be concentrated on the following "theses," each of which will form the subject of a "full-dress debate":—

1. The Cure of Intra-cranial Abscesses produced by Purulent Maladies of the Ear. Reporter: Dr. J. Barr of Glasgow.
2. The General Cure of Aural Disease. Reporter: Dr. Gellé of Paris.
3. The General Cure of Internal Otitides. Reporter: Professor Gradenigo of Turin.
4. The Present State of the Pathological Anatomy of the Labyrinth. Reporter: Professor A. Politzer of Vienna.
5. On the Physiology of the Middle Ear. Reporter: Dr. C. Secchi of Bologna.

Opening of the Congress.

The Aula Magna of the Istituto di Studi Superiori presented a brilliant and animated scene at ten this forenoon, as the President of the Congress, Dr. Grazzi, with Dr. Delstanche on his right and Professor Politzer on his left, took his place on the green daïs. Above him on either side were portraits of Sapolini and Moos, two of the *optimi meriti* of international otology. Nearly every European school was represented, though at the eleventh hour more than one British delegate failed to appear.

President Grazzi opened the proceedings by the announcement of congratulatory messages from the Court of the Quirinal and from other centres, political, educational, and social, all of them welcoming in the name of science and the healing art the distinguished participants, foreign and Italian, in the Fifth International Congress of Otology. The President then delivered his discourse introductory to the business of the Congress. He was listened to throughout with marked attention, and the salient points, easily discernible in the subjoined translation, touched a sympathetic chord in the distinguished auditory.

The President's Address.

"Following the example of my predecessors at Milan, at Bâle, and at Brussels, I, too, with your acquiescence, employ the French language in my inaugural discourse, regretting, however, that on such solemn occasions we no longer speak the language universally understood by our fathers. To few is it vouchsafed, as to His Excellency the Minister of Public Instruction, Dr. Baccelli, to combine in beautiful harmony

[1] Traité de l'Organe de l'Ouïe, Paris, 1683.
[2] De Aure Humana Tractatus, 1704.

Digitized by Google

the study of biological science with the culture of the Roman Classics.

"Professor Voltolini of Breslau, unhappily lost to life and to science, when inaugurating the Second International Congress of Otology, which in September, 1880, met at Milan, remarked that it was not merely by chance that Italy had been chosen for the first assemblage of otologists in Europe. That honour, said our colleague, who, though a foreigner, had Italian blood in his veins—that honour our country owed to its having given birth to Corti, whose discoveries had revealed a new world in the organ of hearing and had wrought the resurrection of our specialty. So true is this that Kölliker wrote: 'Histological investigation of the cochlea begins with Corti, whose excellent monograph should serve as a starting-point for all observers.' The successive meetings of the International Congresses of Otology (begun in America in 1876) were held at Bâle in 1884 and at Brussels in 1888—the first under the presidency of the lamented Dr. Buckhardt of Merian, the second under that of my revered friend Dr. Charles Delstanche, whom all of us with equal pleasure and pride see among us to-day, and of whom Professor Gradenigo, the Turinese otologist, reviewing the proceedings of the Brussels Congress, said: 'To this Belgian, who speaks and writes our language like an Italian, and is, in fact, Italian by sentiment and aspiration, we sons of Italy owe a special debt of gratitude.' To him, therefore, and to another otologist of world-wide renown, Professor Politzer of Vienna, who, as a sympathetic admirer of Italy's artistic beauties, loves our land as if he had been born under its sky, we owe in great measure the high honour reserved for the fatherland of Eustachio, Valsalva, Morgagni, Scarpa, Corti, and Tafani—the honour of hospitably entertaining for the second time in fifteen years the otologists of all civilised nations. I welcome our able masters; I welcome all those who wished Florence to succeed Brussels in the series of International Congresses of Otology. And since to me, *in absentiâ*, was vouchsafed the pre-eminent and undeserved honour of being chosen President of the Organising Committee of this Congress, permit me to thank you to-day from the bottom of my heart.

"During the seven years that have elapsed since you entrusted me with this honourable charge I have ever recognised my inadequacy to its duties, and have often been anxious for the success of the Congress, knowing as I did what difficulties had to be overcome. This only serves this morning to enhance my joy in seeing that the result may be regarded as assured by the number and the distinction of the otologists who, from Europe and America, have come with their contributions to science, contributions the importance of which is *en évidence* in the programme. You know one of those difficulties, and it is a pleasure, on my part, to announce that in you I have found trusty coadjutors to surmount them. When, at Berlin, Rome was selected as the seat of the International Medical Congress, the otologists there assembled resolved to hold the fifth International Congress of Otology eight days before the great Medical Congress. However, as the time for the two meetings approached, some Italian otologists formed a committee amongst themselves, and proposed the suppression of the Florentine Congress and its absorption in the otological section of the Medical Congress at Rome. I kept aloof from these deliberations, not wishing the frustration of this new vote, which did honour to the city of my adoption, and not wishing, moreover, to put myself in antagonism to high-minded colleagues as if I were annoyed at losing the Presidency with which I had been honoured. Dr. Delstanche, who up to the nomination of the definitive president of the new meeting might be considered as still in office, shrunk from the responsibility of destroying the institution of International Congresses of Otology, whose importance and usefulness, scientific and practical, he had insisted on in the discourse with which he inaugurated the Brussels meeting, and he took the sense of all who had assisted at the last Congress and had voted for Florence as the seat of its successor. This *plébiscite* by a large majority resulted in the autonomy of the International Otological Congresses being maintained. Florence was acclaimed as the seat of the fifth of the series, its meeting, however, being postponed till this year so as not to clash with the great Medical Congress at Rome. Such, then, are the reasons why seven years divide the present meeting from the last held in Brussels, while the regular interval between each should be not greater than four years—a regulation observed from the first Congress at New York in 1876 to the fourth at Brussels in 1888. These facts I have recalled in justification of the long delay.

"The joy of seeing gathered together to-day for love of science and humanity the glorious phalanx of working otologists is embittered by sad memories. Here we no longer see colleagues who never failed our meetings till the inexorable shaft of fate had laid them low. Moos of Heidelberg, that genial veteran who at last year's Roman Congress held out to me a tremulous hand with the promise that he would be with us to-day, I leave to be appropriately eulogised by Professor Politzer of Vienna. But let me recall Sapolini of Milan, who believed in the triumphs of otology at a time when the bare mention of the specialty would raise a sardonic smile on medical lips. He died on June 2nd, 1893, after having been in the first International Medical Congresses the champion of an independent section of otology. He made the earliest proposal to that effect at the International Medical Congress in Florence and never tired of repeating it at subsequent Congresses till the medical world, convinced of the progress rapidly attained by otology, at last admitted him to be in the right. I do not speak of his masterly works on aural anatomy and pathology, but I cannot forget the influence he exerted on the happy issue of the Second International Congress of Otology, at which he worthily presided in his own Milan. I wished his likeness to be present with us, if only because the proposal made by him at Bâle and accepted at Brussels to discuss certain subjects previously chosen and studied by the 'reporters' having, to-day for the first time taken effect; we might all of us, if the experiment should turn out a useful one for our labours, remember with gratitude that we owed it to Dr. Sapolini.

"At the vigorous age of fifty years there also died in 1893 Dr. Longhi, one of the secretaries at the Milan Congress, to whose scientific merits should be added this—namely, his having been the first to propose a special asylum for the cure and instruction simultaneously of children suffering from acquired deafness and destined to remain or become mutes if medicine and charity withheld from them a beneficent hand. At this time, too, we have also to lament the loss of Tröltsch, justly styled the father of modern otology. Many of us unquestionably found in the works of the great aurist of Würzburg the first spark which kindled the love of this interesting specialty. Tröltsch, regretting that his advanced age and infirm health prevented his joining us at Brussels in 1888, wrote: 'I wish my colleagues to know, and I count on you, Dr. Delstanche, to inform them that I will follow at a distance with the greatest interest the works of this assemblage, and that my liveliest sympathies are engaged in their efforts.' I call to mind Joly of Lyons, who never failed our congresses till cut off, still young, from the affection of his friends. Familiar with our language, he was the *internuntius* whereby much of our Italian otology was conveyed to France. I cannot close this sad list without a tribute of regret for the two illustrious men who, labouring in a field different from ours, rendered signal service to otology—Helmholtz, who with his powerful genius threw a flood of light on the darkness of the physiology of the labyrinth; and my fellow-student and devoted friend, Alessandro Tafani, pupil and successor of the immortal anatomist, Pacini. Tafani in this school for many years studied in man and the lower animals the intricate structure of the ear, confirming, correcting, amplifying, and even unveiling new secrets in the fine maze of the acoustic organ. Devotion to study hastened undoubtedly the untimely end of the Florentine anatomist, from whose bright intellect humanity might have hoped for important revelations.

"Having completed my task, let me turn your thoughts to the business of our Congress. Otology has made immense strides in the second half of this century, and all of you, in greater or lesser proportion, some in science, some in practice, have contributed to these. Even when importance of any kind was denied to our specialty, it was admitted that otologists had conquered something in the field of aural semeiology and pathology; but all merit was withheld from them in the curative direction which is that which most nearly interests those who suffer, physically and morally, from defective hearing. But to-day, thanks to the progress of surgery, this disparaging assertion is no longer justified, and in otological cures we obtain results certainly not less gratifying than in any other branch of the healing art. The titles of many communications announced for the Congress pointedly reveal the contemporaneous tendencies of otology and, provided we stop short of exaggerating surgical cures, as Lange of Copenhagen justly observes, I believe this

Digitized by Google

advance will raise our specialty still higher in professional estimation. If we shall have contributed to this end we shall be satisfied with our work; and in this hope, which I trust may become reality, I am happy, in the name of his Majesty Humbert I., King of Italy, to declare open the Fifth International Congress of Otology."

The President sat down amid a round of plaudits, and he was followed by other speakers, Dr. Delstanche of Brussels and Professor Politzer of Vienna, the latter pronouncing a highly finished *éloge* on Professor Salomon M. Moos, who, born in 1831 at Randegg and educated at Heidelburg, Prague, and Vienna, was a "magnifique modèle de toute une carrière de labours et d'efforts incessants, faits pour arriver aux sommités de connaissances scientifiques." A pupil of Henle, Hasse, Moleschott, and Chelius, he graduated at Heidelberg in 1856, when he defended his masterly thesis "Ueber den Einfluss der Pfortaderverschliessung auf die Zuckerbildung in der Leber." His "Klinik der Ohrenkrankheiten" (1876), his "Anatomie und Physiologie der Eustachi'schen Röhre (1875), and his "Meningitis Cerebro-spinalis Epidemica" (1881) are worthy of the catholic genius of the physician, who was the first by his translation of Toynbee's great treatise to familiarise Central Europe with the highest results of English otology. I have no space in which to do justice to Professor Politzer's *oraison funèbre*, for such it is, on Dr. Moos, and will simply refer the reader to its reproduction in the official "Atti," where it will be found to rank with Moleschott's monograph on Donders and Mosso's on Ludwig as a beautiful *immortelle* laid by a surviving brother on a colleague's tomb.

After this the "Bureau du Congrès" fixed the order in which the theses were to be taken, beginning with Dr. Gellé of Paris, who, at the sittings, resumed at 3.30 P.M., read a paper on the General Treatment of Maladies of the Ear. He introduced not a few important modifications in traditional practice, pointing out, *inter alia*, the use of massage in certain cases. Having exceeded nearly four times over the fifteen minutes' allowance, he found the audience indisposed to prolong the subject by criticism, and he was succeeded by Dr. Arslau of Padua with a Contribution to the Study of Adenoid Tumours. On this and the other papers that followed Dr. Gellé's, which latter deserves a more detailed notice, I shall have something to say next week.

Florence, Sept. 23rd.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 757.)

THE SITUATION AT PORTSMOUTH.

ONE of the great difficulties at Portsmouth is due to the fact, as already explained, that the Portsmouth Dockyard Medical Benefit Society admits infants and juveniles as well as adults at the uniform rate of ½*d.* per head per week. I have now before me the balance-sheet of this society for the year 1894. There are the medical fund, the management fund, and the reserve fund. The ½*d.* contributions for the year brought in £898 8*s.* 7*d.*, arrears paid during the year £22 3*s.* 8½*d.*, and £2 9*s.* 8½*d.* were transferred from the reserve fund, making a total of £923 2*s.* This was divided among the three medical officers of the society, the first medical officer receiving £381 11*s.* 11*d.*, the second £351 11*s.* 9½*d.*, and the third £189 18*s.* 3½*d.* The management fund amounted to £67 8*s.* 1½*d.*, and is raised by entrance fees and a subscription of 1½*d.* per quarter per member. Then there is a reserve fund, supported by the first month's contributions, to assist in paying medical officers for those members leaving the society when in arrears. This fund amounts actually to £120, and was increased during the year to the extent of £8 13*s.* 6*d.* These figures suggest the questions as to what was the amount of work done for these various sums paid to the medical officers, and how was the work done. The duties of the medical officers are defined in the book of rules as follows: "The medical officer shall be bound to supply all necessary medicines, leeches, dressings, bandages, splints, and whatever may be required for the proper treatment of the disease or hurt, and the due performance of his duties he by his agreement engages to perform; all splints, bandages, &c., supplied by the medical officer to be returned or paid for by the member, and that members are to find their own bottles, and in all cases when able to attend at the surgery; in the event of a change of medical officers one month's notice to be given by the party requiring the same; for such services he received 2*s.* 2*d.* per annum for each member in his district, payable quarterly. Any member requiring medical attendance and unable to attend the surgery, shall give proper notice in writing to the medical officer, with member's residence in full, which should if possible be before 10 A.M., who shall attend to the same without delay." Such is the actual phraseology of the rules. The medical officer who received for the year 1894 the sum of £381 11*s.* 11*d.* very obligingly went through his books, and ascertained that he had given 4650 consultations to the members of the society in his surgery, and had made 1958 visits. Dividing this total of 6608 consultations by the sum received, the fees paid amounted to 1*s.* 1½*d.* per consultation. From this must be deducted the cost of the medicines, etc., which in this case was estimated at about half the total sum. Now it should be observed that since this society was first founded the wages earned at the docks have increased to an extent of about 10*s.* a week, but it has never occurred to the workmen that they might have increased their medical fees in due proportion to the augmentation of wages they had secured. Nor has any attempt been made by the Dockyard Medical Benefit Society to establish a wage limit. On the contrary, the President of the Liberal Union, who is a member of the board of guardians, is employed in the dockyard and also keeps a newspaper shop, is a member of the Dockyard Medical Benefit Society. One of the medical officers of this society is also a member of the board of guardians and has to attend his colleague on the board for the munificent remuneration of one halfpenny per week.

The example of the Dockyard Society is unfortunately spreading. The Rechabites having decided to admit infants and juveniles, the six or seven medical men in their service recently sent in a joint protestation, stating that for juveniles the contributions should be augmented. Children, they urged, required more attendance and medicine than adults; that the proposed fee of 2*s.* 2*d.* per annum for children was insufficient and should be the same as for adults—namely, 4*s.* per annum. This request has been rejected, and the reason given for this refusal is that the average rate of sickness among members is much less than in similar societies which do not adopt the temperance pledge. I have not yet been able to obtain any statistics that prove this contention. On the other hand, I have met a medical officer in the service of the Rechabites who, on the contrary, considered them an unhealthy set of people. The fact that a man is a total abstainer sometimes means that his digestive faculties are so impaired that he could not drink even if he wished to drink. Others very wisely become total abstainers because their parents were excessive drinkers and they fear they may inherit the alcoholic taint. In a word, many persons are total abstainers precisely because their health is not all that could be desired. The Rechabites further give as a reason for refusing to grant the request of their medical officers that their members pass a medical examination before being admitted, and that this is not done by all societies; and, moreover, that "in one society at least in Portsmouth the whole of the family, adults as well as children, are received at the same rate—viz., ½*d.* per member per week." By this, of course, they mean the Dockyard Medical Benefit Society. Thus we have in this reply, written by the secretary of the Rechabites, documentary evidence of the evil wrought by the example of the Dockyard Society. They go on to say that cases of infectious disease are treated at the infectious hospital and accidents at the Landport Hospital, so that their medical officers have not to attend such cases. Having thus refused to make any extra allowance for juvenile branches the secretary of the Rechabites seeks to increase the duties of the medical officers, and this in a very objectionable manner. He adds that the Rechabites "would also respectfully ask their surgeons to request to see members' contribution cards when application is made for medical aid, as they would thereby protect themselves from imposition, and also assist the superintendent in reducing the amount of arrears, which would, of course, put the Tents in a better financial position." Thus the medical men are to act as detectives working on behalf of the collectors of subscriptions, a very unpleasant task which certainly forms no part of medical duties. In the face of this most unsatisfactory reply the medical officers in the service of the Rechabites seem disposed to resign their situations. In that case, the medical profession throughout Great Britain should be warned and made to understand that

Digitized by Google

it would be a dishonourable act to accept any offer that may be made by the Rechabites of Portsmouth.

It is not only the Rechabites who are seeking to admit juveniles, but a very large lodge of the Oddfellows at Portsmouth have now notified their intention to admit infants, and this may also cause the resignation of the medical officers concerned. The medical officer who has received this notification has a very large club practice. He calculates that he is occupied three hours per day in his own surgery receiving club patients, and some of them are sufficiently well off to ride to his surgery on their bicycles. Then he has to see about ten club patients per day in their own homes. Altogether his club patients take up about five hours per day, and for this he receives just upon £1 per day. The dispenser he has to keep and the medicine he has to supply cost him about a third of this sum. Five hours per day at £1 equals 4*s.* per hour, and, deducting the cost of medicine, &c., we get a net profit of about 2*s.* 8*d.* per hour of professional work. The fee for each consultation, including medicine, amounts in this case to from 4*d.* to 5*d.* Nevertheless, the members of these clubs imagine that their medical officers are very well paid and rapidly accumulate fortunes. This is especially the case when the medical man keeps a carriage. They do not realise that a carriage costs 10*s.* a day, and that even at this price it is often about the cheapest way of getting over the twenty or more miles that have to be travelled in the course of the day so as to see all his patients. Then there is the terrible fact that the more thoroughly and conscientiously the medical man does his work the greater the number of patients who flock to his surgery; but, as the number of patients does not increase the amount of the fees, so there is every temptation to neglect the patients and not encourage their visits. It is, therefore, not merely the question of cheapness that members of benefit societies should consider, but rather the kind of attendance they receive. This, again, depends on the individual medical officer, who may or who may not do his very best without any thought of the remuneration he is likely to obtain. The one advantage of doing the work well is that the patients, if thoroughly satisfied, will very frequently continue to consult the club medical officer even if he resigns his position on the club, and then claims the usual fees. There is at least one medical man at Portsmouth who has found it to be no loss to resign his position as medical officer of the dockyard society. Many of his club patients continue to consult him. They are fewer in number, but as they pay proper fees his income does not suffer and he has much more leisure. Two or three families are often preferable to an entire lodge of a club. Also the presence of some ten to twenty club patients waiting to see their medical attendant has a deterrent effect on private practice. Ordinary patients do not like to be confused with club patients, and it is not always easy to sort these and place them in different waiting-rooms. Errors that give offence are often committed. Thus club practice has numerous inconveniences; nevertheless, there are many medical men who lack the courage to give up a small certainty and to incur some risk, even if it be but a slight risk, to secure a general all-round improvement for themselves and the whole of the profession.

Portsmouth, Sept. 20th.

MANCHESTER.

(FROM OUR OWN CORRESPONDENT.)

The Case of Poisoning in Gorton-park.

YOUR correspondent, Dr. MacArthur, seems to think my notice of the case of supposed poisoning by henbane "not quite satisfactory." Any apparent scepticism was not as to the symptoms, for they were not described in the report, but, first, as to the occurrence of henbane in the park; and, secondly, as to the child being attracted by and eating sufficient of such a suspicious-looking plant to cause her death under the impression that it was "green sauce," which she said she had eaten. Dr. MacArthur kindly offers to show me the locality, and says that he can satisfy me that there is a poisonous flora, but he does not say that henbane grows there.

Bequests by the late Mr. D. S. Jackson.

This gentleman, formerly in business here, has left public bequests amounting to £38,000, to take effect after the death of his widow. Of this sum no less than £24,000 go to the benefit of animals. The Manchester Branch of the Royal Society for the Prevention of Cruelty to Animals gets £10,000; the Dublin Society £2000; the Manchester and Salford Cattle Trough Association and the similar London Society get £2000 each; the Battersea Home for Dogs, the Home of Rest for Horses, and the Anti-Vivisection Society, each £2000; while the Homes for Lost Dogs in Liverpool and Manchester get £1000 each. In addition, he left the following sums for the benefit of suffering humanity: £5000 to the Mauldeth Hospital for Incurables, and £2000 each to the Royal National Lifeboat Institution, the Boys' and Girls' Refuges, Henshaw's Blind Asylum, and the National Society for the Prevention of Cruelty to Children. Bequests for the maintenance of pet cats have been made by persons reputed to be eccentric; but Mr. Jackson was a clear-headed, sensible man, who, though always interested in the kind treatment and welfare of animals, was perfectly free from any manifestations of eccentricity, if I except, perhaps, his attitude on the question of vivisection, and this may be put down to want of knowledge. The idea that animals have any claim on our kindness, or that we have any duties towards them, is somewhat new, but is no doubt growing in this country, while it can scarcely be said to have entered the mind or touched the conscience in any other. It will readily be granted, moreover, that the humane treatment of domestic animals is abundantly repaid in the increased efficiency of their service.

Accidental Poisoning.

An excellent article appeared the other week in the *Manchester Guardian* on this subject. It was occasioned by the lamentable accident in Birmingham, where two people were poisoned by strychnine having been given for phenacetine, and draws attention to the "absurd" inadequacy of the Pharmacy Acts. The Registrar-General's returns show that in 1893 587 deaths occurred from the accidental swallowing of poisons and the accidental inhalation of poisonous fumes, of which over 500 belonged to the former category. In 1892 there were 620 cases of fatal poisoning, of which 514 were accidental, and of these 104, or 20·2 per cent., were caused by opium in some of its forms. In 1893 the deaths from this one cause were 93. Chloroform deaths average about 50 and those from carbolic acid about 24, but in this district they have been of late alarmingly frequent, while arsenic is credited with about 15. A long series of cases might be given showing the carelessness with which people treat poisons. "A thirsty policeman drank carbolic acid instead of beer, and about twenty other people—some drunk and some sober—came in this way to an untimely end within the space of eighteen months." Carbolic lotion has often been drunk instead of medicine, and so on almost indefinitely. At one time Burnett's disinfecting fluid, a solution of chloride of zinc, was not infrequently taken in mistake for fluid magnesia; and a lady is living not far from where this is written whose life was for a long time in the greatest peril, both at the time of the accident and subsequently from œsophageal stricture, produced by this cause. The article considers, and very properly, that greater difficulties should be experienced in the purchase of poisons and says that "restrictions should be placed on the sale of carbolic acid, for this is one of the poisons that people toy with most." It would be well if carbolic acid were prescribed less freely now that its place may generally be taken by disinfectants equally efficient and non-poisonous. Weed-killers and vermin-killers provide means for the easy distribution of arsenic and strychnine; and by calling at sundry druggists' shops and purchasing it in small quantities it would not be very difficult to obtain a quart of laudanum. If it is desirable to lessen the facilities for obtaining drink and so reduce the temptation to take it, the same reasoning may be used with equal, if not with greater, force in the case of poisons.

Corporation Show-rooms for Gas Stoves.

Yesterday a commodious building in Deansgate was opened by the Lord Mayor, which has been designed to give intending purchasers the opportunity of inspecting heating and cooking stoves of all makers, so as to encourage the use of gas, and thereby diminish the nuisance of coal smoke. The chairman of the gas committee said they wished to develop to the utmost the resources of the gasworks, in which about £4,000,000 of the ratepayers' money were invested. He wished to reduce the price of gas to 2*s.* per 1000 feet, and to increase the quantity supplied by the penny-in-the-slot meters

Digitized by Google

from 25 ft. to 35 ft. Reduction in the price is necessary if gas is to be largely used for cooking, heating, and for gas engines.

Sept. 24th.

NORTHERN COUNTIES NOTES.

(FROM OUR OWN CORRESPONDENT.)

The Jarrow Cruelty Case.

AT the instance of the National Society for Prevention of Cruelty to Children Leonard George Peters, a registered medical practitioner, was, by the Jarrow magistrates, on Sept. 19th, convicted of gross cruelty to his children, aged respectively ten and five years and one year, and sentenced to three months' imprisonment in Durham gaol. The evidence showed that drink was at the bottom of the case, the wife and children both stating that Peters was kind to them when he was sober, but that he was very often drunk, and then behaved very cruelly to them all.

Newcastle-on-Tyne, Sept. 24th.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Scottish Plumbers' Congress.

THE sixth annual Congress in connexion with the National Registration of Plumbers was held in Dumfries last week. The delegates were received on the opening day in the town hall by the Provost. Amongst those present were Sir Stuart Knill (Master of the Worshipful Company of Plumbers), Sir James Crichton Browne, M.D., and Sir Mark J. Stewart, M.P., who took an active part in the proceedings and participated in a discussion bearing upon the plumbing work in houses. A resolution was submitted and agreed to, urging that in the employment of plumbers preference should be given to registered men. Another resolution which was adopted declared that plumbers, from their practical knowledge and training, were specially fitted for employment as sanitary inspectors. In connexion with the Congress an exhibition of plumber's work was held in the Drill-hall. Sir James Crichton Browne formally opened the exhibition, and in his opening address dwelt upon the intimate relationship of plumbing to the health of the community. In the registration movement he recognised an effort to revive the old feeling of trade credit which was fostered in the Middle Ages by the trade guilds, and he wished them success in their effort to unite old-fashioned morality with modern dexterity. Sir Stuart Knill also addressed the meeting and expressed the hope that we would see in this country a revival of that artistic plumbing of which specimens were to be seen particularly in Germany and Belgium.

The Public Health of Edinburgh.

During the month of August the death-rate in Edinburgh was rather above the average for that month. The reported cases of infectious disease included 197 cases of scarlet fever, 35 of typhoid fever, 21 of measles, and 14 of diphtheria. At the end of the month there were 261 cases in the City Hospital. It may be mentioned in this connexion that there appears to be a considerable number of cases of diarrhœa in the city. Some of them are dysenteric in character, and in some the diarrhœa is accompanied by vomiting. So far as can be ascertained the cases have been readily subdued by treatment.

Prosecutions in Edinburgh under the Pharmacy Act.

A number of prosecutions under the Pharmacy Act were heard last week in Edinburgh in the Sheriff Court. The prosecutions were at the instance of the Pharmaceutical Society of Scotland. The greater number were instituted against assistants in druggists' shops for selling poisons, they not being duly registered druggists. Fines of £5 or less were imposed. Complaints were also made against assistants of two of the leading surgical instrument makers for selling tablets containing bichloride of mercury. In these latter the accused pleaded guilty, but it was explained that the tablets were sold to surgeons for cleaning their instruments, and that it was thought that, as the tablets were a proprietary article, they did not come under the Pharmacy Act. Under the circumstances a fine of £1 was imposed, with £1 1*s.* for expenses. Complaints were also made against two dealers in photographic appliances for selling poisons, they not being qualified druggists; in these cases judgment has been deferred. In some of these prosecutions, as in the cases of the surgical instrument makers and the dealers in photographic appliances, the general feeling will certainly be that something approaching a wrong has been done to those prosecuted. It may be an infringement of the letter of an Act of Parliament for a surgical instrument maker to provide his customers with tablets for rendering his instruments aseptic, but most people will not be prepared to believe that the Act had any such object in view when it was drawn. The course taken by the Pharmaceutical Society in the matter seems to require an explanation, for meanwhile, although technically justified, it will be felt that their action has been ungenerous and unwise. In a case tried in Glasgow last week laudanum had been sold to a boy ten years of age whose mother subsequently poisoned herself, and the principal of the shop in which the sale took place admitted that it was a common practice to sell laudanum to young persons.

The Cost of Small-pox in Edinburgh.

At the meeting of the Edinburgh town council to-day the treasurer's committee recommended an assessment of 2*s.* 2*d.* per pound. The treasurer, in moving the adoption of this recommendation, pointed out that the increase of 1*d.* per pound over last year was brought about, not on account of the ordinary expenditure, but was entirely due to the small-pox epidemic of last year, which caused a deficit of £11,622.

The Proposed New City Hospital for Edinburgh.

At the meeting of the Edinburgh town council to-day the proposal of the health committee to purchase Colinton Mavis Farm for the price of £20,500 as a suitable site for the proposed new city hospital was submitted by the chairman of the committee and seconded by Sir James Russell. The report and the recommendation were agreed to. Attention was drawn to the presence of epidemic disease in some districts of the city, and one of the members thought that sufficient was not being done to prevent infectious disease from spreading. He thought that something should be done to bring them more into touch with the county authorities than was the case at present.

Poisoning by Benzine.

An unusual case of poisoning is reported from Falkirk. A woman who had become suddenly unconscious was found on examination to have swallowed a quantity of benzine. It is presumed that she swallowed this, mistaking it for a mixture she was in the habit of taking for a sore-throat.

Scottish Prison Statistics.

In their annual statement for 1894 the Prison Commissioners report that the number of prisoners committed to prison for that year was 52,658 persons. The increase, which makes the total greater than in any previous year, is largely due to an augmentation in the number of persons committed for drunkenness, and this is attributed to the prosperous state of the country and to the activity of the police. As bearing on this point it is noted that during the three months of severe weather in the early part of the present year the prison population fell to the lowest point on record. The returns also show an increase in the cases of sickness, which numbered 1221, and included 45 cases of influenza and 40 cases of delirium tremens. Twenty-three persons were released on medical grounds, and there were 51 cases of insanity. Of the latter, 40 were discovered to be insane when committed Concerning the department for criminal lunatics at Perth the Commissioners state that Dr. McNaughtan "continues to conduct it with our full approbation," and quote the Visiting Commissioners in Lunacy to the effect that "the state of the work, the condition of the inmates, and the management of the establishment continue to be very satisfactory."

New Fever Hospital for Stirlingshire.

The county council have approved of plans for the erection of a new hospital for infectious diseases near the village of Camelon. The estimated cost is £6450.

The New Asylum at Hawkhead.

The congested condition of their present asylum at Merryflatts has compelled the Govan authorities to push forward the completion of a portion of their new building, though the original plans are far from being realised. The

Digitized by Google

completed portion has been sanctioned for use as a district asylum, and a number of patients have been transferred to it under the care of Mr. Watson.

Scottish Prison Medical Officers' Association.

An association of the medical officers of the Scottish Prison service has recently been formed. The first meeting took place in Glasgow last week.

A Strike of Butchers.

A rather curious struggle has recently been in progress at Motherwell. The butchers of the district decided to boycott the public slaughterhouse in order to compel the authorities to accede to their demand that the whole of a carcase in which tuberculosis is localised should not be destroyed, but only the diseased portion, the remainder being passed as fit for human food. The Commissioners, however, have stuck to their guns and the butchers are now giving up the struggle.

The Falls of Foyers.

The scheme of the British Aluminium Company, which involves the practical destruction of this magnificent waterfall, has excited considerable indignation. An attempt has been made to gain the help of the Government, but it seems that the Secretary for Scotland has no power to interfere. Mr. Ruskin has associated himself with the opposition which is now being organised by the National Trust for Places of Historic Interest or Natural Beauty, under the Presidency of the Duke of Westminster. Any of our English medical friends who desire to do so may join in the protest by writing to the Secretary to the National Trust, 1, Great College-street, Westminster, S.W.

Aberdeen University: the Inauguration of the Mitchell Tower and Students' Union.

The University Court at a meeting last week agreed, in deference to the wishes of Mr. C. B. Mitchell and Mrs. Mitchell, to proceed with the celebrations at the date originally fixed. They will therefore take place on Thursday and Friday, Oct. 24th and 25th, but the proceedings will be somewhat curtailed from the original plan. The order of events will be somewhat as follows. On Thursday the Mitchell Tower and Students' Union will be formally opened. The clock in the tower will strike and a response will be given by the city bells. The custody of the Union will be handed over to the President of the Students' Representative Council, and an address will probably be presented by the students to Mr. C. B. Mitchell. In the evening there will be a grand conversazione in the new buildings. On the Friday the new Graduates' Hall will be opened in the forenoon, and the honorary doctorates will be conferred. In the afternoon the Marquis of Huntly will deliver his rectorial address in the new hall, while in the evening the Lord Rector will be entertained to dinner by the University authorities. The proceedings will be wound up with a students' torchlight procession.

The Health of Aberdeen.

The zymotic diseases notified for last week were: scarlet fever, 24; whooping-cough, 26; erysipelas, 7—making a total of 57, which number is two cases fewer than last week, but there are noticeable a considerable increase of scarlet fever and a decrease of whooping-cough.

Sept. 24th.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The New Dublin Hospital for Infectious Disease.

AT a recent meeting of the guardians of the North Dublin Union a letter was read from the Local Government Board stating that they adhered to an opinion, expressed as far back as 1892, that it was desirable that the guardians of the Dublin unions should have suitably situated hospitals for the reception and treatment of dangerous infectious diseases under their own control and management. Mr. Stafford, the Local Government Board inspector, agreed that it would be best to have a single infectious disease hospital established in connexion with the two unions, but that additional Parliamentary powers would be required for that purpose. He also stated that Sir Charles Cameron was actually preparing a scheme for a joint hospital, to be under the management of a board which would probably consist of the guardians of the North and South Dublin unions, the corporation, and other sanitary authorities. As the scheme of the chief medical officer of health has been almost completed, and as all the sanitary authorities will soon be asked to meet and discuss the matter, the further consideration of the subject was postponed.

Irish Workhouse Reform.

The circular of the Local Government Board addressed to the boards of guardians of Ireland has already had the effect of strengthening the position of some of the medical officers in country districts and of inducing them to direct public attention to necessary reforms. At a recent meeting of the Castlerea board of guardians an order for provisional relief given by the medical officer to a family stricken down by fever of a malignant type was disallowed, the guardians refusing to pay the bill for the relief. Mr. Coen, L.R.C.S. Irel., J.P., &c., stated that he believed himself justified in giving the order as the family was destitute and stimulants were urgently required for the treatment of the disease. He is reported to have said, moreover, that "Mary Leonard aged thirteen years had, since the board's order, died for the want of stimulants." It appeared that the medical officer had notified the relieving official by message and telegram, and then had issued the order himself. As Mr. Coen remarked, "doctors should be allowed a certain amount of liberty in such cases, especially where the people are destitute and in urgent need of stimulant treatment." It is only right to say that ultimately the guardians agreed to pay the amount of the bill, while maintaining their opinion that it was unlawful for the medical officer to have given the order.

Westmorland Hospital, Dublin.

The Lords Justices have appointed Sir Charles Cameron to be a governor of the Westmorland Lock Hospital, in the room of Sir George Porter, deceased.

Board of Superintendence of Dublin Hospitals.

The Lords Justices have appointed Dr. Henry Fitzgibbon to be a member of the Board of Superintendence of the Dublin hospitals, in the room of Sir George Porter, deceased.

Compulsory Retirement of Professors appointed by the Crown.

Some time ago the question of compelling professors and presidents of the Queen's Colleges in Ireland to retire at a certain age was raised by the Order in Council of Aug. 15th, 1890, which placed them exactly in the position of Civil servants, who are compulsorily retired at the age of sixty-five years. Legal authorities differed as to whether this order could be made to apply to professors, and President Moffet of Galway, after having been compulsorily retired, was, on the advice of the English Lord Chancellor (Herschell), reinstated. After this the Treasury appointed a Committee (Lord Playfair, Lord Welby, and Sir Matthew White Ridley) to consider the advisability of fixing an age for the compulsory retirement of professors serving under the Crown. This committee, who took evidence during the past summer, have just reported that, in their opinion, the commission of 1880, upon the report of which to some extent the Order in Council of 1890 was based, did not intend that the limitations of age should apply to presidents and professors of colleges, who are appointed and serve under different conditions from those which prevail in the Civil Service. After pointing out that these presidents and professors are appointed at a maturer age, and have, by the nature of their employment at seats of learning less tendency than Civil servants to become inefficient at the age of sixty-five, and that the Queen's Colleges in Ireland are only to a small extent dependent upon votes in Parliament, being mainly supported out of the Consolidated Fund, and that, in consequence of this peculiarity, they are in more intimate connexion with the executive Government, with which the presidents are in frequent communication as to the working of the college and the efficiency of the professors, who are appointed by the Crown and by whom they can also be dismissed, and that the statutes which govern the colleges also emanate from the Crown and are not (as in other colleges) the product of academic autonomy, the committee are of opinion, taking all these circumstances into consideration, that there should be fixed rules as to superannuation of presidents and professors, and that they should be made by college statutes and not by an Order in Council. The committee recommend that when a professor reaches sixty-five years of age the president of the college should be bound to report to the Government the condition

Digitized by Google

and efficiency of the teaching. If these are and continue to be satisfactory the professor need not be superannuated till he is seventy, but at this age his retirement should be absolute. As to presidents, they advise the age of seventy as the period of retirement, but in case the visitors of the college make a formal report that the college would suffer by the loss of the experience which the president has acquired the committee suggest that the Treasury, and not the Irish Office, should have power to keep him as president for a certain number of years not exceeding five, so that at the age of seventy-five the retirement of a president should be absolute. The committee believe, as the professors are not appointed till middle life, that the addition of seven years to their period of service in calculating the amount of their superannuation obviously tends to secure eminent specialists as candidates for office. The power of voluntary retirement at the age of sixty has also much to commend it in this sense. Such is the gist of the report presented to the Treasury by their committee.

New Infirmary for County Tyrone.

At a meeting held in Omagh on Sept. 20th, the Duke of Abercorn presiding, it was decided that a committee should be appointed to carry out the necessary conveyances for acquiring a site for the new Infirmary on a gentle eminence about a quarter of a mile from Omagh, recommended by the site sub-committee. It seems that up to the present the total sum subscribed is £3000, and it is expected that another £2000 will be raised by the sale of the old Infirmary. Plans for the erection of the new building were then considered and approved of, with the exception of some trivial alterations. The question of the formation of a ladies committee, as a large sum of money will still be needed, was left to the Duchess of Abercorn. The proposed situation of the new Infirmary is an admirable one for a hospital, being on the banks of the Camowen river in the centre of a beautiful and most healthy district.

The Consumption of Alcoholic Liquors in Irish Workhouses.

The Irish Association for the Prevention of Intemperance has issued a comparative statement of the expenditure in intoxicating drink in Irish workhouses during the year ending Dec. 31st, 1893. The expenditure in many local unions is not great. Belfast heads the list with an outlay of £598, North Dublin comes next with £497, then Limerick with £413, Cork £228, and Rathdown £254.

Outbreak of Typhus Fever at Ardboe.

Mr. Robert Burgess, dispensary officer for Coagh, has received a special vote of thanks from the Cookstown guardians for the energetic steps taken by him to check a serious outbreak of typhus fever in Ardboe, on the shores of Lough Neagh, county Tyrone.

The Duties of Medical Officers, Masters, and Matrons in Irish Workhouses.

At the present time the subject of the management of Irish workhouses and their attached infirmaries is attracting a good deal of attention in various parts of Ireland. As an instance of this, I may mention that at the last meeting of the Ballymena guardians the following queries were put before the board by Dr. W. R. Davison, medical officer of the workhouse: "Is it any part of the master's duty or the duty of the matron to transfer a patient from the infirmary to the asylum without a proper certificate from the medical man in charge? I take it that the wards set apart for the insane patients from Belfast are to all intents and purposes a part of the Belfast Asylum for the time being. Is it any part of the master's duty to complete a medical certificate in the case of an insane patient? Is it any part of the master's duty, or the duty of the matron, to say when a patient is fit to be removed from the infirmary, or how long a patient should be retained in, or when a patient should be treated in the infirmary?" Dr. Davison, who was present, said he made no charge at all against the master or matron, but there were certain duties belonging to each of them, and he wanted the matter decided. After discussion, it was decided to enter the word "No" at the end of each query in the medical officer's report, and that in the opinion of the guardians the medical man had preferred no charge.

The Battle of the Clubs at Cork.

It will be in the recollection of the readers of THE LANCET that some time ago all the Cork druggists, with one exception, refused to continue to supply the clubs at contract prices. This was what might have been expected, as for years past the druggists have felt aggrieved at being called on to sell their drugs to rich club patients at the reduced prices charged to the humbler classes. In the exigency of the situation the clubs were glad to find that even one druggist was willing to help them out of their difficulty, and accordingly all their prescriptions went to his establishment. But somehow the clubs and their druggist do not appear to be on harmonious terms, and an official of the clubs has written a letter to the other druggists asking them in peremptory terms whether they will be prepared to enter into contracts with the clubs as heretofore, and stating that if they should contumaciously refuse, the clubs will start an opposition druggist's shop in Cork. The druggists, I am sure, will treat this threat with the contempt it deserves. If the clubs seriously contemplate doing what they say, which I very much doubt, they might endeavour to do one of two things, either to bring in an outside druggist or to raise capital amongst themselves. With regard to the former I cannot see how any respectable firm would be so foolhardy as to open a branch in Cork; with the thorough conviction that by doing so they would for ever alienate the whole medical profession of Cork; and with regard to supplying capital, all I can say is if I wished to invest money I would prefer putting it into a mine in South Africa about which I knew absolutely nothing. The recalcitrant clubs are being cornered more and more every day, and the angry tone of their letter to the druggists is a fair indication that they feel they are playing a losing game. It has been the fixed policy of the profession not to enter into a newspaper correspondence with the club members, but I have reason to believe that the letter of the medical delegates, a copy of which you published last week, has produced a very marked effect on the general public. The charges of boycotting brought against the Cork hospitals by the President of the United Trades' Association have dissipated into thin air. A very forcible letter on the subject addressed to the Mayor by Mr. D. J. Forde, trustee and treasurer of the North Infirmary, has been published in the local papers. The following extract from Mr. Forde's letter is worth reproducing as illustrating the sentiments of the thoughtful public with regard to the President's action:—"In conclusion, I may say the trustees naturally feel much annoyed at the way this matter was brought forward and commented on, while a note of enquiry from the association or others, such as you have sent, would have at once elicited an answer from the trustees; but to be held up to public odium first, and the facts enquired into afterwards, seems discourteous and unreasonable."

PARIS.

(FROM OUR OWN CORRESPONDENT.)

The Remains of the Old Faculty of Medicine.

M. CORLIEU recently read a paper on the above subject before his colleagues of the Academy of Medicine. He tells us that up to the year 1409 the Faculty buildings consisted only of a miserable tenement situated in the Rue des Rats. This street, the possession of which was, judging by its name, disputed by the students and armies of rodents, still exists near the Place Maubert as the Rue de l'Hôtel Colbert. The members of the Faculty then held their meetings either in the space surrounding the principal baptismal font of Notre-Dame, or they paid so much rent for accommodation in the Convent of the Mathurins. In 1469 the Faculty bought a house in the Rue de la Bucherie, and thirty years later constructed a chapel close by. In 1567 a botanical garden was added. These premises included all the ground upon which now stand the houses numbered 13 and 15, Rue de la Bucherie at the angle of the Rue des Rats, the façade measuring thirty metres. No. 13 is now devoted to uses the very reverse of moral, while No. 15 is a public washhouse. In 1617 there was built in the garden an amphitheatre called "Riolan's Amphitheatre," because in its construction were employed the designs of the son of Riolan, the celebrated French anatomist, whose name, by the way, is still associated with the muscles inserted into the styloid process. Frequently recurring inundations, caused by overflow from the neighbouring Seine, having damaged the buildings, 20,000 livres, left for the purpose by Michel le Masle, were in 1678 devoted to the reconstruction of the entrance gate. In 1745 the renowned anatomist Winslow

Digitized by Google

(who, born in Denmark in 1669, died at Paris in 1760) opened the new amphitheatre, built on the site of the old one. This amphitheatre, called the "Amphithéâtre de Winslow," still stands. It cost 52,016 livres 10 sous. Nowadays the remains of these ancient buildings are scarcely recognisable, being put, as they are, to less noble uses. The benches and professors' tribunes are now replaced by laundry utensils, the first floor has been converted into a cheap lodging-house, and the amphitheatre seems to frown sadly at this degradation. M. Corlieu terminates his most interesting communication by asking: "Par suite de quel contrat tacite Esculape a-t-il cédé une partie de son temple à Vénus?"

Treatment of Pneumonia by large doses of Digitalin.

M. Franc (Congrès Français de Médecine Interne held at Bordeaux) strongly recommends for the treatment of pneumonia the following plan of medication: the first day the administration of one or two milligrammes of crystallised digitalin, the solution used being Petit-Mialbe's 1 in 1000 solution; the second day one milligramme of the alkaloid is given, and if necessary the same dose is exhibited daily for a few more days. On the second or third day considerable improvement is stated to be observable, the disease appearing in some instances to be aborted. The happy effects of the digitalin are specially noticeable in infectious, adynamic types of pneumonia, where a manifest change for the better in the general condition is plainly observed on the second or third day in spite of the persistence of physical signs. It is claimed for the digitalin treatment that improvement is closely followed by rapid convalescence.

Sept. 24th.

ROME.

(FROM OUR OWN CORRESPONDENT.)

The Celebration of the 20th.

As behoves a "carnival people"—the name given to them by a distinguished compatriot of their own—the Italians were quite equal to the festive commemoration of the "silver wedding" of Rome with the new kingdom. The preparations had been well matured, and the result from the holiday-making point of view was a brilliant success. Conspicuous among the events of the day was the speech of Signor Crispi at the unveiling of the monument to Garibaldi, a fine rhetorical effort and in all respects worthy of the statesman in whose hands the destinies of Italy are now placed. Apart from the political aspects of the occasion—with which I am not concerned—there were not a few incidents specially gratifying to the profession, and, indeed, to all who have at heart the well-being, moral and material, of the youngest of the Great Powers. Professor Todaro, who fills with such acceptance the chair of Anatomy in our University, was quite within the mark when, at the opening of the Concorso Ginnastico (athletic competition), he congratulated the Italian youth on the progress made in physical education—in all, to put it briefly, that is implied by the "mens sana in corpore sano." Then, again, the proceedings of the Congresso Nazionale delle Pubbliche Assistenze were worthy of its president, the great sanitary engineer of Spezia, Signor Carlo Verde; of its vice-president, his Excellency Dr. Guido Baccelli; and of the other office-bearers and participants: Dr. Panizza, assessor to the municipality in the Department of Public Hygiene; the Hon. Signor Silvestrelli, whose work in hospital rehabilitation is well known; Professor Aurelio Costanzo, and Major Lombardo, M.D. Certainly the sanitary regeneration of Italy is a question of prime importance for her present and still more for her future, and it is reassuring to find, among the duties she feels imposed on her in celebrating the twenty-fifth anniversary of the consummation of her unity, that that of ministering to the health conditions of her people is not relegated to an inferior post. *Au reste*, the day passed off without untoward incidents of any kind—none of the collisions and violent outbreaks which on similar occasions have filled the hospitals with cases of "cutting and wounding," or worse, having been reported at the "Consolazione" or "San Giacomo."

The Italian Society of Internal Medicine.

The Società Italiana di Medicina Interna will hold its annual meeting this year in Rome from the 14th to the 16th of October. The programme includes two full-dress debates, which, according to the secretary's circular now before me, will turn (1) on Sero-therapy and (2) on the Falling-off of Nutrition in the Human Economy. The first will be introduced by Dr. Pio Foà, Professor of Pathological Anatomy and Bacteriology in the University of Turin, and Dr. E. Maragliano, Professor of Clinical Medicine in the University of Genoa. In the second Dr. Enrico de Renzi, Professor of Clinical Medicine in the Neapolitan School, will lead off the debate. The other items of the agenda paper have much to attract the profession, and those representatives of British schools who may be in Rome about the middle of next month might do worse than look in on this annual field-day of their Italian brethren. All information as to reduction in railway fares and other facilities open to participants at the Congress may be had from the secretary, Professor Lucatello, 40, Via Galata, Genoa.

Baccelli and Virchow.

As I close this letter I am informed, from the Ministry of Public Instruction, that his Excellency Dr. Baccelli has received numerous telegrams from educational institutions and medical schools, Italian and European, participating in the commemoration of the 20th and auguring increased prosperity to the interests, moral and material, for which the absorption of Rome into the Italian kingdom constituted a new departure. The following, of which I give the *ipsissima verba*, comes from a source peculiarly welcome to young Italy in general and young medical Italy in particular:—"Caldissimi auguri di felicità e saluti.—VIRCHOW."

Sept. 21st.

VIENNA.

(FROM OUR OWN CORRESPONDENT.)

The Reform of Medical Study.

THE various boards are just now deliberating on the reform of medical study. The present system is due to the late Professor Langer, who was medical adviser to the Ministry for the Home Department. According to these regulations a five years' course is necessary for obtaining a diploma, and during this time the student has to attend classes in anatomy and physiology (one half-year each), medicine and surgery (four half-years), obstetrics and ophthalmology (one half-year). With respect to the examinations, those in zoology, mineralogy, and botany may be passed at any time. After the close of the second year the student is admitted to the so-called first Rigorosum, consisting of practical examinations in anatomy and physiology, and theoretical examinations in anatomy, physiology, physics, and chemistry. The second and third examinations must not be passed before the close of the fifth year, after which time the student, on producing evidence of class attendance, is admitted to the final examinations. The second Rigorosum consists of a practical and a theoretical part, the former comprising the subjects of pathological anatomy and medicine, and the latter those of pathological anatomy, medicine, materia medica, and experimental pathology; there are also included two additional examiners in diseases of children and laryngology, who alternate. The third Rigorosum consists of practical and theoretical examinations in obstetrics, ophthalmology, and surgery, and a theoretical examination in forensic medicine. The lecturers on otology and syphilis alternate as additional examiners. After having passed these examinations, the Faculty grants to the student the degree of M.D. These regulations are obviously antiquated, their principal defect being that no attention is directed to matters of such great importance as public health and bacteriology, examinations in these subjects being open only to men who have already graduated and aspire to the position of a public official. It is now proposed that the examinations in zoology, mineralogy, and botany should be discontinued, but that a thorough knowledge of practical chemistry should be required, an innovation upon which much stress is laid by the boards, for chemistry daily produces new remedies (as many as 282 in the past year), and the practitioner ought to have an idea of their composition. The principal point, however, has reference to clinical instruction, because for a number of years complaints have been made of the imperfect practical knowledge of the students, an evil which is due to the spirit of centralisation prevalent in this country. According to this system, clinical teaching in medicine is limited to three

Digitized by Google

clinics, and in surgery to two clinics. No wonder that the old amphitheatres of the General Hospital are overcrowded, and that a space hardly sufficient for 250 persons is occupied by 600 or 700. The boards, therefore, advocate that clinical instruction should be decentralised, that the chief physicians, extraordinary professors, and *docenten* should be allowed to read lectures, and that the students should have more frequent opportunities of seeing clinical cases. It is also recommended that slight operations should be entrusted to surgical students, a system which has already been adopted in the clinic of Professor Wölfler in Prague. An examination in bacteriology ought also to be combined with that in pathological anatomy, and the study of syphilis should be obligatory.

Medical Advertising.

In spite of the endeavours of the Medical Chamber the tribe of advertising practitioners still flourishes, and the newspapers are filled with the announcements of specialists who promise to credulous sufferers "a radical cure for all secret diseases, even the most inveterate, and restoration of lost or impaired sexual vigour." Some of these persons pay to newspapers £100 annually for the daily insertion of their advertisements, but their number has already decreased, and some of them have left Vienna for Budapest, where this abuse has not yet attracted much notice. Against those who continue such dishonourable practices the Medical Chamber will take the most energetic measures, and will specially direct its attention to the undue influence of the lay press in medical matters. This mischief has already advanced to such a degree in Vienna that the lay press has the power of making medical celebrities, and that systematically. Many a young member of the profession has become a person of note in consequence of the exertions of journalists with whom he is acquainted, and even leaders of our school lend themselves to interviews, the substance of which is printed next day for the pretended purpose of popularising medical science. Every day the newspapers mention the return of this or that practitioner after taking a holiday—a notice which is paid for like any other advertisement. It is singular that the Medical Chamber does not restrain a medical man from making such a personal announcement, provided that it is not repeated more than three times; it will act in the interest of the profession by abolishing this concession.

The School of Medicine, University of Vienna.

According to the prospectus for the coming winter session, which has just been issued, 260 classes and courses will be held by 29 ordinary professors, 38 extraordinary professors, and 85 *privat-docenten* and assistants. The details are shown in the following table:—

Subject.	Classes.	Ordinary professors.	Extraordinary professors.	Privat-docenten and assistants.
History of Medicine	2	1	—	—
Anatomy	10	2	2	1
Physiology	12	2	2	1
Pathology	17	2	4	4
Pharmacology	6	1	—	2
Medicine...	62	4	7	26
Surgery	49	2	9	14
Otology	11	2	1	3
Ophthalmology	23	2	2	6
Midwifery	32	4	5	15
Syphilis	18	2	2	9
Mental Diseases	8	2	2	2
Chemistry	9	3	2	1
Veterinary science	1	—	—	1
Totals...	260	29	38	85

Last summer session the school was attended by 2213 students, among whom there were 1480 ordinary, 351 extraordinary, and 382 occasional students.

Cholera in Galicia.

According to official returns 35 cases of cholera, with 20 deaths, occurred between Aug. 23rd and Sept. 20th. During the last week 22 cases, with 10 deaths, have been reported—3 in Berczovica, 14 in Tarnopol, 4 in Wertelka, and 1 in Obelnica; the disease is raging in the districts of Brody and Rohatyn, but in Tarnopol it is limited to the town-gate Podole, which is inhabited by the Jewish population. After the occurrence of a case the relatives sometimes leave their home and settle in other parts of the town, but as this practice throws difficulties in the way of sanitary control an enumeration of all the inhabitants of the above quarter has been ordered. Travellers coming from Russia are subjected to a sanitary inspection in the frontier towns of Brody, Podwoloczyska, or Stojanow, and soldiers who arrive at Vienna from Galicia have to remain five days under supervision.

Sept. 21st.

Obituary.

SURGEON-GENERAL JOHN IRVINE, M.D. ABERD.,

HONORARY PHYSICIAN TO THE QUEEN.

WE much regret to announce the death, on the 21st inst., at his residence, Longridge-road, South Kensington, of Surgeon-General J. Irvine, M.D., Honorary Physician to the Queen, late of the Army Medical Staff. Dr. Irvine entered the army as an assistant surgeon in 1849. He saw a good deal of active service during the Indian Mutiny, having been with Havelock's column in the Royal Artillery (Maude's division) and present in several actions. From November, 1857, to March, 1858, he was with General Outram's force, and was present at the siege and capture of Lucknow by Lord Clyde, the relief of which has just been celebrated by the annual anniversary dinner. He also received a medal and clasp for service in Burmah in 1886. The late officer acted as head of the sanitary branch of the Army Medical Department under the Director-Generalships of Sir William Muir and Sir T. Crawford; he went to Egypt as Principal Medical Officer of the force in 1883, and was present at Cairo during the last cholera epidemic in that country; he subsequently went to Madras as Principal Medical Officer of Her Majesty's forces in that Presidency, and retired from the service in 1888. Dr. Irvine was promoted to the rank of Deputy-Surgeon-General in 1876 and to that of Surgeon-General in 1883; and in 1885 he was appointed Honorary Physician to the Queen. The late Surgeon-General Irvine was a very popular officer, and his death will be much regretted by a wide circle of friends and acquaintances. He was sixty-seven years of age at the time of his death.

LEONARD WILLIAM BURTON, L.R.C.P. LOND., M.R.C.S. ENG.

ONE of the special risks attendant on medical practice has just been made apparent by the lamented death of Mr. L. W. Burton of Burton-on-Trent. This gentleman, who was a successful student at St. Thomas's Hospital and became qualified in 1886, had almost ever since been in practice with his uncle, Mr. Perks of Burton, where he made many friends and gained the confidence and esteem of his patients in all ranks of life. With a well-established position among the practitioners of the town and the additional opportunities for useful work afforded by his connexion with the Infirmary, where he was one of the assistant surgeons, everything seemed to indicate a prosperous career, but these expectations were not to be realised. While assisting at an operation on Aug. 21st he had the misfortune to wound his thumb, and septicæmia ensued, terminating fatally on Sept. 6th. The funeral took place on Sept. 9th in presence of a very large and sympathetic company, the officiating clergy being the Vicar of Burton and the Vicar of St. Paul's Church. Mr. Burton, who was only in his thirty-sixth year, has left many surviving relatives to deplore his untimely and tragic decease.

VACCINATION GRANT.—Mr. Fredk. W. Lewis, Public Vaccinator of the No. 1 District of the Llandovery Union, has received the Government grant for efficient vaccination for the eighth time.

MEDICAL TRIAL.

SERIOUS CHARGE AGAINST A MEDICAL MAN.

MR. JOHN MINTER, the borough coroner for Folkestone, formally opened an inquiry on Thursday, Sept. 19th, touching the death of Gertrude Fanny Fletcher, who died in London on Sept 9th. Having briefly referred to the causes which led to the inquiry being held Mr. Minter adjourned the proceedings until Saturday, the 21st inst.

On Saturday, when the inquiry was resumed, Mr. Geoghegan and Mr. Bruce, instructed by Mr. Arthur Vernon, appeared for Dr. Wight, and Mr. Hempson, with Dr. A. G. Bateman, on behalf of the Medical Defence Union, watched the proceedings for Mr. Whitehead and Mr. Hannah. Mr. W. Lenn Walter, solicitor, represented Mr. Fletcher, the husband of the deceased.

The brother of the deceased woman having given evidence identifying the body,

Mary Anne Hawken was called and sworn. She said: I am a nurse in the habit of attending confinements. I am a widow, have had eleven children, and have had large experience in attending confinements. I was engaged to attend the deceased in her confinement. I took up my residence to attend her on Aug. 31st. On Saturday, Sept. 7th, Dr. Wight called in the forenoon part of the day. Mrs. Fletcher went to bed at night between six and seven. Dr. Wight was sent for later in the evening because she was rather worse and pains were coming on. Dr. Wight could not attend, and Mr. Whitehead came about eleven o'clock. He remained till about five o'clock in the morning. He examined the deceased and said her labour was very slow and he would send her a couple of pills to cause her to sleep. Mr. Whitehead came again next morning about ten and again examined the deceased. He said labour had just set in and that he would go round and see Dr. Wight and send him. Dr. Wight came between twelve and one, and he examined the deceased. He said when he left he would come in again in the afternoon. I examined the deceased myself, and in my judgment everything was right for an easy labour. At half-past four I sent for Dr. Wight. Dr. Wight arrived about six, accompanied by his son. He went into the bedroom where the deceased was, and sent me down to the drawing-room to his son for the chloroform. The son returned with me to the bedroom. Dr. Wight asked for two jugs of hot water. I left the room and returned with one. The chloroform had then been administered and Mrs. Fletcher had gone off. Dr. Wight attempted to use the forceps, inserted one blade and tried to insert the other. They continually came back. After some little time I said, "What is the matter with the instruments—won't they lock?" He made no answer. After a short time he tried to press the baby back into the body with his hand; I asked him what he was trying to do, and he replied that there was an obstruction between the baby's head and the bones, and part of the afterbirth was in the way. I said to him, "I can't make that out." He said that the child was so twisted that he wanted to get at the feet. I said, "That you will never do." He was about half an hour attempting to force the forceps. He again applied the instruments, after trying what he could do to turn the child. They did not lodge on that occasion. He then let go the instruments on to the bed. He tried to remove the obstruction with his hand. When he dropped the instruments he said to his son, "Go for Whitehead." He seemed to me to be very stupid, as though he had just recovered from a drinking bout. Mr. Whitehead came about ten minutes or a quarter of an hour after. When Mr. Whitehead arrived he said, "Well, nurse, what's the matter?" I said, "I don't know, doctor; something serious, I am afraid." Dr. Wight's son said to Mr. Whitehead, "She is strong. We had something to do to get her off. She has had six ounces of chloroform already." Mr. Whitehead examined the deceased in the ordinary way, and I saw two pieces of what I believed to be the neck of the womb protruding from the parts. Mr. Whitehead took them in his fingers and said, "What's this?" Dr. Wight said, "That has been the obstruction—part of the afterbirth between the baby's head and the bone." Mr. Whitehead said, "This is not a bit of the afterbirth," and he ran his fingers through them. They then both left the room and went into an adjoining room. They returned together in a few minutes. Mr. Hannah was sent for and arrived in about ten minutes. When he came Dr. Wight and Mr. Whitehead were present. I could not hear what Mr. Hannah said. I left the room for about ten minutes and on my return I went for a candle. Mr. Whitehead said, "Come, nurse, where's your scissors and thread?" The baby was born and on the bed. I took the baby up and Mr. Whitehead severed the cord. The afterbirth came in a very few minutes. The afterbirth, which I examined, was perfect. Mr. Whitehead gave me directions as to attending the deceased during the night, but nothing as to cleansing. I said to Mr. Whitehead, "I'll attend to Mrs. Fletcher." He replied, "Don't you do anything until Dr. Wight and myself come in the morning." He did not say why. I said, "I must do something in the way of changing her and cleaning up some of this. Don't you think I had better use a syringe?" He said she was to remain as she was until Dr. Wight or himself returned in the morning. Dr. Whitehead came on Monday morning about eight or nine o'clock. He examined the deceased and said I was not to cleanse her. He came again about five o'clock in the afternoon. Mr. Hannah came in on Monday about two o'clock. When Mr. Whitehead came in the afternoon he did not give me any directions. Dr. Griffith came just after midnight on Sunday night. When he arrived Mrs. Fletcher was very ill. She died on Monday night between eight and nine. Mr. Whitehead was in the room when she died. Just previous to her death I left her for a few moments to attend to the child. In my absence she got out of bed on to the floor. Mr. Whitehead was downstairs. He returned with Mr. Fletcher, and they took Mrs. Fletcher up and laid her on the bed. Mr. Whitehead said, "Oh, my God, that's her womb on the floor," and he put it back. She was quite cold below her knees at two o'clock. After she died I said to Mr. Whitehead, "This is a very serious case," and he said, "Now, nurse, now, nurse." Mr. Fletcher said, "Nurse is quite right." I said to Mr. Whitehead, "If I am not a witness against the man in this world I shall be in the next."

By Mr. Geoghegan: Dr. Wight appeared dazed and stupid, and this is my reason for thinking he was recovering from a drunken bout.

John Henry Fletcher, the husband of the deceased, in the course of his evidence, said he told Mr. Whitehead he did not like the appearance of Dr. Wight, and asked him to take the case up. Mr. Whitehead said he did not wish to take the case out of Dr. Wight's hands. He went to Mr. Hannah, and he declined on the same grounds. He then went to see Dr. Wight and told him he desired further advice. Dr. Wight mentioned the name of Dr. Griffith, and directed Mr. Fletcher to go to his surgery for the address. He requested an audience with Dr. Wight later through the speaking-tube. He declined to grant it; he said he had done with the case, or words to that effect. "You have got Whitehead—keep him." On the arrival of Dr. Griffith he told witness his wife was in a very critical state. After his wife's death he (Mr. Fletcher) desired to have her body examined before interment, and called on Dr. Wight and gave him notice of this intention. Dr. Wight said, in effect, that he did not hold himself responsible for the deceased's death. Dr. Wight said Mr. Whitehead had ruptured her. Dr. Wight said he should not come to Folkestone, and he knew of no one at Folkestone to represent him. He (Mr. Fletcher) went to the Inspector of Police for the district in London and made a communication to him of the circumstances previous to the body being conveyed to Folkestone.

By Mr. Geoghegan: Dr. Wight appeared in a dazed and confused condition.

In reply to questions by the jury Mr. Geoghegan said Dr. Wight was at home seriously ill, and had arranged with Mr. Whitehead to take his night work.

Mrs. Hawken, recalled, was asked by Mr. Hempson if Mr. Whitehead at any part of the case used the instruments. She replied, "He did not."

Florence Fletcher, sister of Mr. Fletcher, said she was with her sister-in-law on the Saturday, and was in the drawing-room when Dr. Wight and his son came.

By Mr. Geoghegan: Dr. Wight appeared to be dazed and stupid, and in my opinion he was the worse for drink.

Charles Capon, a chemist, and Nelson Perry, a bricklayer, gave evidence as to Dr. Wight appearing in a dazed and stupefied condition on Sunday night, Sept. 8th.

Mr. Henry E. Whitehead was called and detailed his connexion with the case. He gave evidence as to breaking the waters. "I simply broke the membranes," he said, "and did not rupture anything. I simply did what is done in every confinement." This was on Saturday.

By the Coroner: You heard the nurse's evidence.—Yes. Did you say when you took the pieces in your fingers, "What is this?"—I cannot remember. I cannot say whether her evidence is true or not. Dr. Wight was excited and nervous.

By Mr. Geoghegan: In the spring of this year Dr. Wight was laid up; he had a severe attack of influenza, followed by insomnia, and he had been taking large quantities of chloral and bromide. That would make a man in a dazed and stupid condition?—Yes. And he had asked you to take his night work?—We had a constant arrangement, not necessarily for night work. His articulation was thoroughly clear. He did not smell of drink. Anything of the nature of chloral or morphia would place a man in much the same position as one in drink.

By the Coroner: The chloral has a stupefying effect on a person. Do you think a man in that state ought to attend a confinement?

Mr. Geoghegan objected to the question. Witness was there to show that Dr. Wight was sober, but suffering from an illness that might be mistaken for drunkenness. Could a man in such a state distinguish from right and wrong?

The Witness: Chloral has a thoroughly deteriorating effect upon the brain.

Mr. Frederick Richard Hannah said he felt it his duty after making an examination to call the husband's attention to the serious and critical condition of his wife. The bowels protruded through a rent which was about two inches in length in the posterior wall of the vagina. The rent must have been caused by some violence.

By Mr. Geoghegan: I knew that Dr. Wight had been very ill and should not have been at work. A man suffering from an overdose of choral and bromide would show the same symptoms as he would in the case of alcohol.

Dr. W. S. A. Griffith said: I was called by Mr. Fletcher at midnight and arrived about 1 o'clock on Monday morning. Mr. Whitehead was there to meet me, and he explained to me the nature of the case, and asked my opinion as to what could be done. I examined Mrs. Fletcher and satisfied myself of the correctness of his statements. The bowels had been carefully replaced, and I advised that nothing further could be done unless she rallied. She was then in a very feeble condition. I was called again on Monday evening and arrived just after her death.

By Mr. Geoghegan: Lacerations of the same parts may occur spontaneously, but I do not think this was so in this case.

By the Coroner: Had the instruments been used skilfully the laceration should not have taken place. I should like to add that I am of opinion, from the medical evidence that has been given, that the child's head remaining high up so long made the laceration more easy than it would otherwise have been.

The proceedings were then adjourned till Tuesday, Sept. 24th, Mr. Geoghegan being again assisted by his junior, Mr. J. A. Bruce.

The evidence taken on the preceding Saturday being read, Mr. Whitehead desired to make a correction. He did not state that the womb had fallen on the floor. He did not pick up anything from the floor; but on putting Mrs. Fletcher back to bed he replaced a portion of the protruding bowel.

Mr. Dobbs, called, said that at the request of Mr. Fletcher he attended at Folkestone Cemetery and examined the body of Mrs. Fletcher, and saw some sewing of the body which he could not account for.

The Coroner stated that the sewing was done after death.

The Witness: In company with Dr. Barry I made a thorough post-mortem examination on Sept. 19th. I found the body in an advanced state of decomposition. The abdomen was considerably distended and there was bruising and laceration of the external genitals. The vulva was sewn up. The perineum was ruptured. Between the stitches there were small pieces of bowel protruding. That was externally. Internally all the organs were soft and decomposing. The cervix was swollen, congested, and ragged-looking. The posterior lip was almost completely torn off. The peritoneum called the retro-uterine pouch was torn squarely off the back of the uterus, making a lateral slit through which three fingers could be passed. Passing through this slit into the vagina was bowel to the length of 3 ft. 6 in. In the anterior wall of the rectum was a lacerated wound 6 in. long.

Mr. Barrett gave similar testimony. He said: The perineum was ruptured extensively, leaving only a ring formed by the sphincters.

Digitized by Google

Behind the womb there was a slit in the peritoneum connecting with the vagina. The body of the uterus was large, soft, and flabby, about eight inches in length. Inside the surface was rough, and there were several small blood clots. The site where the placenta had been detached was easily discerned. The neck of the uterus was swollen and ragged-looking, the posterior lip having been almost completely torn off. At the back of the uterus above the cervix the peritoneum was torn off transversely. The anterior wall of the rectum was split up to the extent of about six inches. The body of the uterus was perfectly fixed with its ordinary ligaments in its natural position.

The Coroner intimated that this would finish the evidence, and remarked that he thought it fair to Mr. Wight not to call him as a witness. Mr. Geoghegan, however, decided that his client should be put into the witness-box, and he was examined by Mr. Bruce.

Dr. George Wight said: I attended Mrs. Fletcher on the Saturday, and I had seen twenty or thirty patients on that day, visiting them at their homes. On Sunday morning Mr. Whitehead came to me and made a report of the condition of the deceased. He said she was going on slowly, but that he had ruptured the membranes. On the afternoon of Sunday I went home at two o'clock, took a strong dose of chloral, and lay down on my bed. I had been ill since Feb. 22nd, suffering from the after-effects of influenza, insomnia, and loss of appetite. I had been twice away—once to Eastbourne and once to Brighton. When I attended Mrs. Fletcher I inserted the lower blade of the forceps and tried to put on the upper blade, but failed. In withdrawing it I think I must have ruptured the vagina. I had a previous attack of influenza in 1891. I have had it severely on two occasions. On Saturday and Sunday I was unable to take my usual food, chiefly living on milk. I have been in practice thirty years, and during that time I have attended about 5000 cases of confinement. This is the only case in which I have had unusual difficulty, although I have had difficult cases. I have never had a case before that required a judicial inquiry.

Did you use all competent skill on this occasion?—I did my best. I was suffering on the Saturday night from vertigo. I took a strong dose at 2 P.M. on Sunday of chloral bromide and digitalis.

By the Coroner: Will you tell the jury why you declined to go on with the case when Mr. Fletcher requested you on the Sunday?—I considered Mr. Whitehead had taken my place.

But you were engaged for the case?—Yes; but Mr. Fletcher preferred Mr. Whitehead. I greatly regretted that I did not attend.

By Mr. Geoghegan: I only had a little whisky and water since noon on Saturday.

Mr. Geoghegan then, by permission of the coroner, addressed the jury.

The Coroner, in a lengthy summing-up, took occasion to express his surprise that the inspector of police in London had not instituted inquiries, and also that the six or seven medical men in Folkestone who had been notified of the matter had not communicated with him.

The jury returned a verdict of "Manslaughter" against Dr. Wight, whom the coroner admitted to bail. Dr. Wight was on Wednesday, the 25th, formally charged at the Clerkenwell Police-court and remanded. The magistrate also admitted him to bail.

Medical News.

UNIVERSITY OF DURHAM: FACULTY OF MEDICINE. The following candidates have passed the examination for degrees in Medicine and Surgery at the College of Medicine, Newcastle-upon-Tyne, being the second examination for the degree of Bachelor in Medicine:—

Anatomy, Physiology, and Materia Medica.—First-class Honours: George Grey Turner, College of Medicine, Newcastle-upon-Tyne; Edwin Gilbert Emerson Arnold, M.R.C.S., L.R.C.P., St. Thomas's Hospital. *Second-class Honours:* Vincent Burrow, St. Mary's Hospital; Robert Fletcher Moorshead, Bristol Medical School; Thomas Streatfeild, M.R.C.S., L.R.C.P., University College Hospital, London; and Henry Coxon Coxon, College of Medicine, Newcastle-upon-Tyne. *Pass List:* Joseph Ellis Baker and Frank Antbony Cooke, College of Medicine, Newcastle-upon-Tyne; William Wilkie Deans, Yorkshire College, Leeds; Charles Edward Fenn, King's College; John Maxwell Gover and Charles Johnson, College of Medicine, Newcastle-upon-Tyne; Ralph Albert Rogers Lankester, University College Hospital, London; Walter Herbert Lister, William Byron Milbanke, and George Whitson Middlemiss, College of Medicine, Newcastle-upon-Tyne; Francis Pope, Mason College, Birmingham; Horace Clare Regnart, Guy's Hospital; and Bertram Crossfield Stevens, St. Thomas's Hospital.

PRESENTATION.—Mr. David S. Park, F.R.C.S., L.R.C.P. Edin., of Houghton-le-Spring, Durham, has been the recipient of a valuable scarf-pin from the members of the ambulance class in that town, in appreciation of his services to them.

SMALL-POX AT SHEPTON MALLET.—An outbreak of small-pox has occurred at Shepton Mallet workhouse. The medical officer of health (Mr. J. T. Hyatt) reported to the guardians at their last meeting that all the cases in the infectious hospital were progressing favourably. One fresh case had been admitted from outside the workhouse on Sept. 17th, and on the 21st the attendant had developed the disease. The total number of cases at present in the hospital was five. The inhabitants of West Shepton have sent a petition to the guardians complaining of the close proximity of the infectious hospital to the roadway and dwellings.

AT the Norwich Church Congress Canon Venables will preside over a meeting of the Funeral Reform Association on Monday, Oct. 7th, at 4 P.M., when papers will be read on Earth-to-Earth Burial, State-regulated and Free Burial, and Child Insurance. Tickets can be had on application to the Honorary Secretary, Westow Vicarage, York. The meeting is to be held at the Maid's Head Hotel.

THE JENNER RELICS.—A subscription has been opened in Bristol to provide for the purchase and retention in Bristol of the celebrated collection of relics belonging to Jenner in connexion with his introduction of vaccination, the idea of which he is said to have conceived in 1780. The collection at present belongs to Mr. Frederick Mockler of Wotton-under-Edge, and was exhibited by him at the Bristol Exhibition in 1893, and also more recently in London, where it attracted a considerable amount of attention. Earl Fitzhardinge heads the subscription list with £10 10*s*. This seems a very opportune time for purchasing this interesting collection, as the centenary of the discovery of vaccination is in 1896, and the Russian National Health Society has already announced its intention of celebrating the event.

A NEW HYDRAULIC STEAM LIFEBOAT.—It is a subject for general satisfaction that the service of steam power has at last been utilised with a fair promise of success in the navigation of coast lifeboats. A full description of the latest example of her class, the *President van Heel*, just built on the Thames, has been given in the daily press. It is therefore superfluous for us to quote in detail the evidences of persevering ingenuity and of adaptation displayed in her structure, which have so far been fully confirmed by her official trials. As yet the number of steam lifeboats belonging to this or other countries is very small. For obvious reasons the construction of a boat uniting in herself the qualities of strength and buoyance in the degree possessed by the type of craft used hitherto, but worked by steam, is a work of no ordinary difficulty. It is to be hoped that the seagoing efficiency apparent on a fair-weather trial will stand the severer test of storm experience. If so, we may congratulate ourselves upon a new departure of the most encouraging augury. No longer dependent upon the uncertain aid of steam tugs or the muscular power of human arms, however willing, the means of rescue at sea must become so much the more efficient and certain in their issue. To the rescued the consequent saving of time may make all the difference between illness or death and a rapid restoration of health and energy.

CASE OF SUICIDE AT THE MIDDLESEX HOSPITAL.—On Wednesday, Sept. 25th, at the coroner's court, Paddington, before Dr. Danford Thomas, an inquiry was held into the causes of the death of Alfred Brown, late porter of St. Saviour's Hospital, Osnaburgh-street, who committed suicide by jumping from the window of a ward on the third floor on Friday at Middlesex Hospital, where he was admitted last Thursday, Sept. 19th. He succumbed to his injuries on Saturday, Sept. 21st. Eliza Crofts, in charge of St. Saviour's Hospital, said the deceased was their porter. He seemed very steady, but had lately been low and unsettled. Dr. Wm. Wanklyn, the house physician, said the patient was admitted for general debility and muscular tremors. In his opinion he was suffering from an early stage of general paralysis of the insane. He saw him on the morning of the occurrence, but had not the slightest idea he would do anything, although he suspected something was wrong mentally. He saw him after the fall when he was quite sensible. He died of shock and collapse.—Ellen King, nurse in Forbes Ward, Middlesex Hospital, said she was in the ward a little after twelve, and had just been dressing the patient's foot. She went down the ward to take something away, and when she came back from the lavatory she saw him get out of bed and make for the window, which was half open. He put his foot on the chair, and opened the window wide. She ran up the ward, and got hold of his shoulder; he was half out, and in his nightshirt. She tried to hold him, but he got out head first, breaking the window. She put her arm out, and held him as long as she could; one of the patients helped her. Then he dropped fifty feet to the ground.—John Pullenger, porter at Middlesex Hospital, deposed to seeing the patient fall.—The Coroner having summed up, the jury returned a verdict of "Suicide while of unsound mind."—Dr. Wanklyn expressed his sympathy with the relatives on behalf of the Middlesex Hospital.

FOOTBALL CASUALTIES.—During a game at Durham on the 14th inst. a Bede College student fractured his femur.—On Saturday last, in a match between the Preston North End and Celtic teams at Preston, the North End centre forward sustained a compound fracture of the kneecap, and was removed to the infirmary.

LITERARY INTELLIGENCE.—The coming publishing season promises to be a prolific one. Messrs. Baillière, Tindall, and Cox announce as ready on Oct. 1st a new Manual of "Physiology," by Professor Stewart, with coloured plates; a new edition of Peddie's "Physics"; new works by Dr. John F. H. Broadbent on "Adherent Pericardium," by Professor Max Knies on "The Relations of the Eye to Diseases of the Body," and by Dr. Sachs on "The Nervous Diseases of Children." They will also publish an authorised translation of Professor Haab's well-known "Atlas of Ophthalmoscopy," with sixty-four coloured plates, by Mr. Ernest Clarke, and a translation of Professor Kaposi's classic on "Diseases of the Skin."

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

BERESFORD, R., M.D. Glasg., L.R.C.P. Lond., L.R.C.P., L.R.C.S. Edin., has been reappointed Medical Officer by the Oswestry Rural District Council.

BRUNTON, T. L., M.D., C.M. Edin., B. and D.Sc., F.R.C.P. Lond., has been appointed Physician to the St. Bartholomew's Hospital.

CAINE, N., M.B., C.M. Edin., has been appointed Junior House Surgeon to the Infirmary for Children, Liverpool.

COSENS, F.R.S., L.R.C.P. Lond., M.R.C.S., been appointed Medical Officer to the principal Lodge of Oddfellows in Dorchester.

FOX, J. A., L.R.C.P. Lond., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., L.S.A. Lond., has been appointed Medical Officer and Public Vaccinator for the No. 1 District and Workhouse, Penzance Union, vice A. W. T. Steer, resigned.

FREER, J. H., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for Rugeley.

FYFFE, W. KINGTON, M.B., M.R.C.P., has been appointed Assistant Physician to the City of London Hospital for Diseases of the Chest, Victoria Park, E.

GARRETT, J. H., M.D. Durh., B.S., D.P.H. Camb., has been reappointed Medical Officer of Health for the Borough of Cheltenham.

GIBVAN, DAVID W., M.B., M.S. Glasg., has been appointed Medical Officer for the Cardiff South District of the Cardiff Union.

HELBY, E. H., M.R.C.S., L.R.C.P., D.P.H., has been appointed Resident Medical Officer to the Croydon Borough Hospital.

HERRINGHAM, W. P., M.D. Oxon, F.R.C.P. Lond., M.R.C.S., has been appointed Assistant Physician to St. Bartholomew's Hospital.

HIGGINSON, GEO., B.A. Camb., L.S.A., has been appointed Medical Officer to the Workhouse and the No. 1 Sanitary District of the Church Stretton Union.

HOYLE, J., M.B., C.M. Edin., has been reappointed Medical Officer for the Soyland Urban District.

LEIGH, ALBERT, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Malpas Sanitary District of the Whitchurch Union, Salop.

MCCOMBE, R., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer for the Bassingbourne District of the Royston Union.

MACDONALD, JAS., M.B., C.M. Edin., has been appointed Medical Officer of Health for the Carlisle Rural Sanitary District, vice Hall, deceased.

MCDOUGALL, ALEX. H., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Workhouse of the Parish of Birmingham, vice Barber, resigned.

MONTSERRAT, K. W., M.B., C.M., has been appointed House Surgeon to the General Hospital, Great Yarmouth.

MOORE, T., M.R.C.S., L.M., has been appointed Medical Officer for the Hazel Grove, Handforth, and Brennington Districts of the Stockport Union.

NESBITT, R., L.R.C.P., L.M., L.R.C.S. Irel., has been appointed Medical Officer of Health by the Sutton-in-Ashfield Urban District Council.

PARE, J. W., M.D., C.M. Edin., L.D.S., has been appointed Lecturer on Dental Anatomy and Physiology to the National Dental Hospital, vice Sidney Spokes, resigned.

REYNOLDS, H. D., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Medical Officer for the Pembroke Urban District.

SANDFORD, H. V., L.R.C.P. Lond., L.F.P.S. Glasg., has been reappointed Medical Officer of Health for the combined Rural Districts of Bromyard, Hereford, Ledbury, Leominster, and Weobley.

SELLS, C. J., L.R.C.P. Lond., M.R.C.S., has been reappointed Medical Officer for Worplesdon, the Guildford Union.

SKIPWORTH, H., L.R.C.P., L.M. Irel., M.R.C.S., has been reappointed Medical Officer of Health for the Quorndon Urban Sanitary District.

SWAILES, THOS., M.D. St. And., L.R.C.P., L.M. Edin., M.R.C.S., has been reappointed Medical Officer of Health, for South Crosland.

TYLECOTE, J. H. L., M.B., B.Ch. Vict., has been appointed House Surgeon to the Lancaster Infirmary.

WALKER, ALLAN, M.B., C.M. Glasg., has been appointed Medical Officer of Health for the Weetslade Urban Sanitary District.

WARD, FRANCIS, M.B., C.M. Edin., has been appointed Second House Surgeon to the East Suffolk Hospital.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Assistant Physician, to see out-patients.

HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.

LONDON FEVER HOSPITAL, Liverpool-road, Islington, N.—Assistant Resident Medical Officer. Salary £120 per annum.

LONDON HOSPITAL, Whitechapel, E.—Medical Electrician.

METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant Surgeon.

MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer, for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.

PARISH OF ST. MARY'S, Islington, N.—Resident Assistant Medical Officer and Dispenser at the Workhouse and Infirmary, St. John's-road, Upper Holloway. Salary £80 per annum, with rations, apartments, and washing, or allowance in lieu of same. Applications to the Clerk, Guardians' Offices, St. John's-road, Upper Holloway, N.

PETERBOROUGH INFIRMARY AND DISPENSARY.—A Physician, a Surgeon, and an Assistant Physician.

ROYAL ALEXANDRA HOSPITAL FOR SICK CHILDREN, Dyke-road, Brighton.—House Surgeon. Salary, £80 per annum, with board, lodging, and washing.

SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary £100, with board and residence.

SWANSEA HOSPITAL.—House Physician, for one year. Salary £50 per annum, with board, lodging, and laundress.

WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—Resident House Surgeon. Salary £50 per annum, with board, lodging on the premises, and washing. Applications to the Hon. Sec., 25, Lord-street, Liverpool.

Births, Marriages and Deaths.

BIRTHS.

ADDISON.—On Sept. 22nd, at Westbourne, Tenterden, Kent, the wife of W. B. Addison, B.A., M.B., B.C. Cantab., M.R.C.S. Eng., L.R.C.P. Lond., of a son.

BENJAMIN.—On Sept. 17th, at The Old Hall, Dorrington, near Shrewsbury, the wife of J. K. Kinsman Benjamin, M.R.C.S. Eng., L.R.C.P. Lond., of a daughter.

EMERSON.—On Sept. 23rd, at Melton House, Belgrave, Leicester, the wife of D. N. Bomford Emerson, M.B. Dubl., of a daughter.

HAMERTON.—On Sept. 4th, at Southampton-street, Covent-garden, the wife of G. A. Hamerton, F.R.C.S. Eng., of a son.

LANGRAN.—On Sept. 19th, at The Lawn, Axminster, Devon, the wife of W. Langran, L.R.C.P. Edin., of a daughter.

POWER.—On Sept. 22nd, at Hoe Park-terrace, Plymouth, the wife of Surgeon-Major E. R. Power, Army Medical Staff, of a daughter.

VERNON.—On Sept. 18th, at Drayton, Boscombe, the wife of Arthur Heygate Vernon, F.R.C.S., of a daughter.

MARRIAGES.

DIXON—NADIN.—On Sept. 18th, at St. James's, Barton-under-Needwood, Thomas Dixon, M.R.C.S., L.R.C.P., of Rocleshall, Staffs, to Emilie Maude Duclos, third daughter of the late N. Guy Nadin, of Stapenhill, near Burton-on-Trent.

ROWSE—HADDOW.—On Sept. 21st, at the Wesleyan Church, Barry-road, Camberwell, S.E., Edward Leopold Rowse, L.R.C.P. Lond., M.R.C.S., of Putney, to Elizabeth (Grace), second daughter of Nathaniel Haddow, of East Dulwich.

SPRIGGE—MOSS.—On Sept. 16th, at St. James's Cathedral, Toronto, Samuel Squire Sprigge, M.B., B.S. Cantab., eldest son of the late Squire Sprigge, of Watton, Norfolk, to Mary Ada Beatrice Moss, second daughter of Charles Moss, Q.C., of Toronto, Canada.

WEBB—CLARK.—On Sept. 25th, at the Parish Church, Cheadle, Cheshire, by the Rev. F. A. Macdona, M.A., rector, assisted by the Rev. S. Gauden, Rector of Coal Island, County Tyrone, Frank Webb, L.R.C.P., M.R.C.S., Newcastle, Staffordshire, son of James Webb, Brooklands, Cheadle, to Annie Louisa, second daughter of the late Ledlie Clark and Mrs. Clark, Park House, Cheadle, Cheshire.

DEATHS.

BAILLIE.—On Sept. 19th, at Gloucester-walk, Campden-hill, Kensington, W., George Baillie, M.D., of Holmwood, Uddingston, formerly Deputy-Inspector-General of Hospitals of H.M. Madras Medical Service, aged 70 years.

IRVINE.—On Sept. 21st, at Longridge-road, South Kensington, Surgeon-General John Irvine, M.D., Honorary Physician to the Queen.

STACEY.—On Aug. 21st, at Durban, Port Natal, William Henry Waterhouse Stacey, M.R.C.S. Eng., L.R.C.P. Edin., recently of Grimston, King's Lynn, in his 33rd year.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

"COMMON-SENSE HOMŒOPATHY."

DR. J. M. MOORE has sent to the *St. Helens Newspaper and Advertiser* a copy of his book, showing that homœopathy is the only scientific treatment by drugs. The correspondent who sends us the cutting seems delighted with the compliment expressed in the review and with the system too. We must not blame him too severely. Homœopathy shows best in newspapers, like other vaunted systems.

Mr. Angus E. Kennedy.—Our correspondent is right. There is no way of preventing such gross quackery "while patients allow themselves to be so gulled." The number of fools, if not so great as in Mr. Carlyle's time, is still large.

MEDICAL EXAMINATIONS IN PARIS.

To the Editors of THE LANCET.

SIRS,—I wish to know what fees have to be paid by a medical student at Paris for examinations and what other charges are incurred, and whether it is compulsory to pass an examination in arts; if so, of what nature this examination is. I should feel very greatly obliged if you could either give me the information I seek or refer me to some one from whom I could obtain accurate information.

I am, Sirs, yours truly,

Sept. 24th, 1895. A STUDENT.

INDIAN MEDICAL SERVICE.

Rubicon.—We cannot within reasonable limits reply to all our correspondent's questions, but will do our best. The Indian Medical Department is a good service. Entrance into it is by competitive examination. The difficulty of securing an appointment will naturally depend upon the number of vacancies to be filled and the number of candidates competing for them at the time. The examination is a good one; but a properly educated man of average abilities would, we think, have a fair chance of success. It is, of course, impossible to say whether the climate would agree with him or not. An officer can with prudence live upon his pay. The depreciation of the rupee is owing to the present rate of exchange, and affects those who have to remit money home, not those who spend their pay in the country. Those who succeed in getting civil appointments and civil surgeoncies at Indian stations have good professional opportunities and advantages. Young officers have generally at first to do military duty for a time, and they can, if they like, remain in military employ. If our correspondent has no definite opening in this country, and desires to enter one of the services, we think the Indian Medical Service offers many advantages. For the terms and other particulars our correspondent is referred to the Students' Number of THE LANCET, published on Sept. 7th, and to the Military Secretary at the India Office, Whitehall.

G. P. K. G. writes: "In reply to the inquiry of 'Horseflesh,' made in THE LANCET of Sept. 21st, I do not think he could find a more useful work than that written by Captain M. Horace Hayes. It is entitled, 'Soundness and Age of Horses,' and is published by Messrs. W. Thacker and Co., 87, Newgate-street, E.C. The price of the volume is, I believe, 8*s.* 6*d.*"—*Mr. R. Emmett* (Portsmouth) strongly recommends "'Horses and Stables,' by Lieut.-General Sir F. FitzWygram, Bart., published by Messrs. Longmans, Green, and Co., price 5*s.*, as likely to suit the requirements of 'Horseflesh.'" Of this book also *Medicus*—who, by the way, gives its price as 2*s.* 6*d.*—avers: "It gives everything anyone wants to know on the subject."

Accounts.—We know of no legal sanction for such charges. A creditor can enforce payment of his debt when it is due. If he allows time to elapse before doing so, it is not the fault of the law.

Anxious should consult a qualified medical practitioner. This course should have been followed at first.

"UNITED BROTHERS-IN-LAW AND MEDICAL ADVERTISEMENT."

To the Editors of THE LANCET.

SIRS,—With regard to a newspaper paragraph referring to me which you reprint in last week's issue of THE LANCET kindly allow me to state: 1. That it appeared absolutely without my knowledge. I in no way knew of or connived at its production nor inspired either its matter or manner. 2. That on its being brought to me by a friend the next morning I immediately went to the editor of the paper, pointed out to him the impropriety, and asked him to insert a disclaimer stating that the paragraph was published without my knowlege or consent. He was quite courteous, but declined to do this, standing upon his right to publish news about anybody or anything at his own discretion in the interests of his paper and its readers. He also pointed out to me what was quite plain—that few would believe a disclaimer; most would look upon it as a manifest artifice and a finish to the advertisement. Now, unless I had sent a town crier round with his bell, I do not quite know how I could do more in this not very important matter. I sincerely hoped that the unpleasant incident was closed, and the paragraph and all its faults dead and forgotten, until I saw THE LANCET yesterday.

I am obliged to your correspondent whose zeal for the honour of the profession spotted the offence so promptly, and whose sole object was, I am sure, to afford me through you this opportunity of setting myself right with my brethren, and remain, Sirs,

Yours faithfully,

Beachfarm-rd., Southsea, Sept. 25th, 1895. THOS. H. LEADBEATER.

*** We do not see what more Mr. Leadbeater could have done and we have pleasure in publishing his letter.—ED. L.

DIPLOMAS IN PUBLIC HEALTH.

To the Editors of THE LANCET.

SIRS,—Can you kindly give me any information as to which is the best degree in public health or sanitary science for a would-be candidate for the post of medical officer of health to obtain before offering himself for election? The D.P.H. Camb., seems to be completely discounted by rural sanitary authorities, if one may judge by the treatment meted out to the deluded diplomates who travelled from the four quarters of the kingdom to the meeting of a certain rural district council. Eleven candidates were present, nine held the D.P.H. Camb., and a tenth had previous experience of the work, but the eleventh—unqualified in sanitation—was elected. How are the rejected ones to improve their chances for the future? I am, Sirs, yours obediently,

Sept. 25th, 1895. CANTAB.

MEDICAL MEN AND ADVERTISING DENTISTS.

IT is very remarkable to see in the newspapers puffing testimonials to advertising dentists written by medical men. There are two such testimonials in the *Deal and Walmer and Sandwich Mercury*. How is the profession of dentistry to be raised if members of the profession of medicine sanction such a system of advertising as they would be ashamed to use in their own case?

U. C. H.—The usual charge for a practice or part of one is two years' purchase. Our correspondent can make the calculation for himself. His long services as an assistant may entitle him to special consideration.

T. B. G.—We never recommend individual practitioners. Our correspondent should consult his own medical man.

LAMP ACCIDENTS.

To the Editors of THE LANCET.

SIRS,—At the present moment when inquiries are being made as to the cause of lamp accidents I think my experience may help a little. I have now been accustomed to the use of lamps for over thirty years and have never had any serious accident. I have used both cheap and dear lamps with equal results, but I am convinced that had I always used a cheap oil with a low flashing point I should have had more than one serious accident, consequently I am driven to the conclusion that the danger lies in the oil and not the lamp.

For the benefit of your readers I give notes of the following occurrences. A glass lamp was taken upstairs to warm a bedroom. After a time the house was found to be full of smoke. On investigation the wick of the lamp was found to have slipped down into the oil chamber, where it lay smouldering and sending out dense volumes of smoke. The lamp was carried into a bath-room and placed in a bath full of water. A large glass duplex lamp hanging in my surgery fell from its fastenings and was, of course, completely smashed. The lamp went out and no harm was done except a horrid mess. Going into my surgery one morning I found a lamp which was kept burning all night completely enveloped in flame, the oil-gas issuing from the union for screwing the burner on to the holder. I took a piece of flannel and wrapped it round the lamp, putting the flame out. My groom, who had charge of the lamps, told me he had once before found the lamp in flames and had put it into a bucket of water and at the same time gave me the key to the solution of the question, why no serious accident had resulted? He asked me why it was that when at home he happened to spill any oil if he applied a lighted match it at once caught fire and burnt away, but that if he did the same with my oil the oil put the match out. I told him I thought it was because he used the cheap oil with a low flashing point usually sold by oil carts, while I used a better oil with a high flashing point (of course I explained to him the meaning of the term), and I think your readers must come to the same conclusion.

I am, Sirs, yours truly,

Sept. 24th, 1895. H. J.

LAVAGE OF THE STOMACH AS A PRELIMINARY TO ANÆSTHESIA IN OPHTHALMIC OPERATIONS.

To the Editors of THE LANCET.

SIRS,—In the operations for the extraction of cataract where it is necessary to induce general anæsthesia, a certain risk of escape of the vitreous humour always accompanies the subsequent vomiting; and although in hospital practice it is easy to see that the patients are properly prepared for chloroform narcosis, the same does not always hold good in private practice, where from motives of mistaken kindness food is often surreptitiously given. In a case of cataract extraction, after the induction of anæsthesia, I washed out the stomach, and by that means removed a very good breakfast, and the anæsthesia passed off without any vomiting. A preliminary lavage would in any case remove the mucus which accumulates in the stomach in the early morning, and must contribute itself in no small way to produce vomiting. It is my intention in subsequent cases of a like nature to effect a preliminary lavage.

I am, Sirs, yours faithfully,

Concordia, Argentine Republic. S. L. WOOLMER.

THE LEGAL VALUE OF THE USUAL BOND.

To the Editors of THE LANCET.

SIRS,—I am informed that quite recently a judgment was given in a London court to the effect that the usual bond between principal and assistant not to practise was illegal and valueless, or to that effect. Will you kindly inform me in THE LANCET if this is correct, and if so, where I can see it or get a copy of it?

I am, Sirs, yours faithfully,

Sept. 16th, 1895. ENQUIRER.

*** The cases bearing on this point are very numerous—too numerous, indeed, to be cited here. The broad result is that such a bond, if the restriction be confined to a reasonably limited district, will be upheld; but if it be attempted by this means wholly to prevent the practitioner bound by it from practising at all, or to exclude him from an area extending beyond the reasonable requirements of the case, the agreement on this point will probably be set aside.—ED. L.

L. M.—If our correspondent will consult his own medical man he will no doubt obtain the information he seeks.

TOMATOES AND CANCER.

To the Editors of THE LANCET.

SIRS,—There is a very prevalent and firm belief, not by any means confined to the more ignorant classes, that tomatoes have a tendency to produce cancer. An authoritative statement in THE LANCET by some physician of eminence—or, if possible, by more than one—as to whether there is or is not a foundation for this belief, would, I venture to think, be of public utility. Possibly some of your readers may be able to trace its origin.

I am, Sirs, yours faithfully,

Sept. 23rd, 1895. J. F. C.

*** There is no evidence of such association.—ED. L.

DOES ILLNESS HAVE ANY BENEFICIAL EFFECT ON ITS SUBJECT?

To the Editors of THE LANCET.

SIRS,—I should be greatly obliged if any of your readers could give me instances (1) of an individual enjoying better health after an illness than before; and (2) of one disease diminishing the intensity of, or actually removing, another disease.

I am, Sirs, faithfully yours,

Devonshire-street, W., Sept. 24th, 1895. HARRY CAMPBELL.

Medical Diary for the ensuing Week.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).

TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).

WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).

THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.).

FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).

SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).

At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY.—OBSTETRICAL SOCIETY OF LONDON.—8 P.M. Specimens will be shown by Dr. Duncan and others. Papers:—Dr. T. G. Stevens and Dr. Griffith: Notes on the Variation in Height of the Fundus Uteri above the Symphysis during the Puerperium, the Conditions which influence this, and the Practical Conclusions which may be drawn from such Observations.—Dr. G. D. Robinson: On certain Micro-organisms of Obstetrical and Gynæcological interest.

During the week marked copies of the following newspapers have been received:—*Westmorland Gazette, New York Medical Review, Nottingham Guardian, Redditch Indicator, Grimsby News, Hawick Express, Western Weekly News, Shrewsbury Chronicle, Wolverhampton Chronicle, Sheffield Telegraph, Leamington Spa Courier, Worcestershire Echo, Hull Daily Mail, Norfolk Daily Standard, Eastern Morning News, Birmingham Gazette, Manchester Courier, Scotsman, Leicester Post, City Press, Sussex Daily News, Vegetarian, Freeman's Journal, Northern Echo, Newcastle Leader, Manchester Guardian, Brighton Gazette, Liverpool Daily Post, Leeds Mercury, Times of India, Builder, Yorkshire Post, Pioneer Mail, Architect, Bristol Mercury, Citizen, East Anglian Daily Times, Liverpool Courier, Newry Telegraph, Sanitary Record, Local Government Chronicle, St. Bartholomew's Hospital Journal, New York Times, West Middlesex Standard, Reading Mercury, Weekly Free Press and Aberdeen Herald, Mining Journal, Hertfordshire Mercury, Local Government Journal, Le Temps, Le Courrier de la Presse, Surrey Advertiser, Fife News, Northern Echo, Norfolk Standard, Lincolnshire Echo, South-Eastern Herald, Kenilworth Advertiser, Huddersfield Examiner, Evening Telegraph (Dundee), &c., &c.*

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

BENGER'S FOOD

For Infants Invalids and the Aged

AWARDS.

GOLD MEDAL, International Health Exhibition, London, 1884.
FIRST ORDER OF MERIT AND MEDAL (Highest Award), Adelaide, 1887.
HIGHEST AWARD, Medical and Sanitary Exhibition, London, 1882.
FIRST ORDER OF MERIT AND MEDAL, Melbourne, 1888.

Notice to the Medical Profession.

BENGER'S FOOD is *not* predigested—as appears to be erroneously supposed by some medical men. It consists of a highly nitrogenous wheaten meal, cooked and impregnated with a suitable proportion of the natural digestive principles of the pancreas. When mixed with warm milk, according to the directions on each tin, these principles convert the farinaceous elements of the food into soluble dextrines and sugar; they further modify, but do not fully peptonise the casein of the cow's milk. This modified casein forms small flocculent curds, instead of hard indigestible masses, in the stomach of the infant, the condition of the casein resembling that of human milk. The fat is entirely unaffected. In this way the digestive organs of the infant are merely relieved of the excessive strain placed on them by the ingestion of ordinary Foods, whilst there is abundant work left to ensure their proper development.

The practical experience of those medical men who prescribe it, and of thousands of mothers, has proved that not only does the infant thrive on Benger's Food almost, or quite, from birth, but that when the time comes for the gradual substitution of other aliment the digestive organs, instead of being weak and atrophied, are healthy and vigorous, and much better able to perform their functions than those of children whose stomachs have been kept in an irritable condition by unsuitable food.

MEDICAL OPINIONS.

"*Mr. Benger's admirable preparations.*"—THE LANCET, March 25th, 1882.

"*Deserving of the highest praise, and only require to be made known to the profession to ensure their extensive employment.*"—THE PRACTITIONER, February, 1883.

"*Few modern improvements in Pharmacy have done so much as Benger's Preparations to assist the Physician in his treatment of the sick.*'—THE MEDICAL PRESS, June 13th, 1883.

"*Benger's Preparations have deservedly a very high reputation and are all largely used.*"—THE MEDICAL TIMES AND GAZETTE, September 8th, 1883.

"*Benger's Food is a preparation, devised on original lines, and which we can speak of in the highest terms. ..... Infants do remarkably well on it, and it is most suitable for many conditions in adults and old people. ..... There is certainly a great future before it.*"—THE ILLUSTRATED MEDICAL NEWS, December 22nd, 1888.

"*Undoubtedly a great advance on any previous attempt in this direction. It is palatable and excellent in every way. We have given it in very many cases with the most marked benefit, patients frequently retaining it after every other food has been rejected. For children who throw up their food in curdled masses it is invaluable.*"—THE LONDON MEDICAL RECORD, March 15th, 1882.

BENGER'S FOOD may be obtained in Tins of leading Chemists, &c., everywhere; wholesale of all wholesale houses, or of

REPORT OF THE ACADÉMIE DE MÉDECINE OF FRANCE.

Apollinaris

"THE QUEEN OF TABLE WATERS."

"The results of the recent investigations "in Paris and the Report of the Académie "de Médecine of France have placed "Apollinaris Water at the head of all the "waters examined for purity and freedom "from disease germs."

NESTLÉ'S CONDENSED SWISS MILK

THE RICHEST IN CREAM.

PERCENTAGE OF BUTTER FAT.

Six Samples of NESTLÉ'S MILK bought at random at six different Shops, and analyzed by Mr. OTTO HEHNER, late President of the Society of Public Analysts, contained AN AVERAGE OF

13.13 PER CENT. OF BUTTER FAT.

Sample Tin sent free to the Medical Profession on application to HENRI NESTLÉ, 48, Cannon Street, London, E.C.

G. & G. STERN'S PREPARATIONS.

ZALONES.

Lozenges with a basis of Chlorate of Potash, Milk Sugar, Gum Arabic, and Liquorice. Each Zalone contains one minim of Pumiline Essence and one minim of Menthol. An agreeable and efficacious remedy for irritation of the throat, bronchi, &c. Invaluable for the immediate relief of coughs, catarrh, &c. **In Boxes, at 1s. 1½d.**

PUMILINE.

PUMILINE ESSENCE.—An essential oil distilled from the needles of the Snow-grown Pine of the Alps. Very useful in all throat, bronchial, and lung affections, as an inhalation or internally. **In Bottles, at 1s. 6d. and 2s. 6d.**

PUMILINE EXTRACT.—A watery extract from the leaves of the Snow-grown Pine. Used in baths for muscular rheumatism, &c. **In Bottles, at 1s.**

PUMILINE LINIMENT.—An Embrocation for external use in rheumatism, sciatica, sprains, &c., containing Pumiline, Olive Oil, and Chloroform. **In Bottles, at 1s. 9d.**

PUMILINE OINTMENT.—An Unguent made of Lanoline and Pumiline; used for skin affections. **In Pots, at 1s. 1½d. and 2s. 9d.**

PUMILINE JUJUBES.—For coughs, and for throat and lung trouble. Made of Gum Arabic and Glycerine. Each Jujube contains one minim of Pumiline Essence. **In Boxes, at 1s. 1d. and 2s. 3d.**

PUMILINE DRY INHALERS.—Very convenient for inhaling the Pumiline Essence. **Price 1s. 6d. each.**

PUMILINE PLASTERS.—Prepared with Pumiline Extract. **Price 1s. 1½d. each.**

PUMILINE WOOL.—Price 2s. per Packet.

PEPSALIA.

The Digestive Table Salt.

Used with food as, and instead of, ordinary table salt, it initiates digestion and ensures the proper assimilation of the food. **In Bottles, at 1s. and 2s.**

NARISSA.

A nourishing Food for general use, as well as for Infants, Children, and Invalids.

Narissa is an extremely palatable Food, prepared on scientific dietetic principles, for breakfast or supper, instead of tea, coffee, or cocoa. It is preferable to any Meat Essence or Extract, and as a Food in place of oatmeal porridge or other farinaceous Foods. It is suitable for persons of all ages, whether in health or otherwise. It is very rich in albumen, in fat, and in phosphates. The amount of unconverted starchy matter is as low as is consistent with healthy digestion. **In Tins, at 7d. and 2s. 6d.**

Please send Postcard for Samples, Literature, Copy of Analytical Reports, &c., which will be forwarded free of charge.

CASSELL & COMPANY'S ANNOUNCEMENTS.

NEW AND RECENT VOLUMES.

A New and Original Work on Surgery.

NOW READY. THE FIRST VOLUME OF

A SYSTEM OF SURGERY.

BY VARIOUS AUTHORS.

Edited by FREDERICK TREVES, F.R.C.S.

With Two Coloured Plates and Several Hundred Original Woodcut Illustrations by CHARLES BERJEAU, F.L.S., and others.

"We must heartily congratulate all those who have been associated in the publication of this volume on the great measure of success they have attained. It is a thoroughly reliable text-book, accurate, fully abreast of current knowledge, and quite equal to any of its rivals. We anticipate that if the second volume equals this one in merit, the work will meet with great and deserved success."—THE LANCET.

TO BE COMPLETED IN TWO VOLUMES, PRICE 48s. VOL. II. IS IN ACTIVE PREPARATION.

*** A Prospectus giving Contents and Specimen Pages of this work will be sent post free on application.

Now in the Press, price 21s.

INJURIES AND DISEASES OF THE GENITAL AND URINARY ORGANS.

By HENRY MORRIS, M.A., M.B. Lond., F.R.C.S. Eng.

[*Profusely Illustrated.*

New Edition, Revised and Enlarged, Illustrated, 12s. 6d.

DISEASES OF THE JOINTS AND SPINE.

By HOWARD MARSH, F.R.C.S.

Price 10s. 6d.

DISEASES OF THE EAR.

By A. MARMADUKE SHEILD, M.B. Cantab., F.R.C.S. Eng.

With Four Coloured Plates and Thirty-four Woodcut Illustrations.

"The whole work is admirably concise, free from pedantry, and if at times tinctured with dogmatism it is a dogmatism which is essentially shrewd and practical. It will be found a safe guide, of convenient size, and eminently readable."—BRITISH MEDICAL JOURNAL.

FOURTH EDITION, Revised, now ready, in Two Volumes, price 21s. With Illustrations.

A MANUAL OF MEDICAL TREATMENT, OR CLINICAL THERAPEUTICS.

By I. BURNEY YEO, M.D., F.R.C.P.,

Physician to King's College Hospital, and Professor of Clinical Therapeutics in King's College; Examiner in Medicine, Royal College of Physicians.

"A book which deserves, and will doubtless command, a wide circle of readers, who will appreciate its value and utility."—THE LANCET.

"This work, with its information always well up to date, may be warmly recommended, as its use will help to disseminate a knowledge of rational therapeutics in the strictest meaning of the term."—BRITISH MEDICAL JOURNAL.

*** *A Catalogue of Cassell & Company's MEDICAL and CLINICAL MANUALS will be sent post free on application.*

An Address
ON
MEDICINE: ITS PAST AND ITS FUTURE.

Delivered at St. Thomas's Hospital on the occasion of the Distribution of Prizes to the Students in the Medical School on Oct. 2nd, 1895,

BY SIR EDWIN ARNOLD, M.A., K.C.I.E., C.S.I., &c.

GENTLEMEN,—The first impulse of a very busy man when he has been asked to deliver an address is undoubtedly to excuse himself as politely as he can. That impulse may be described as automatic and instinctive. I have read how in 1837 Dr. Marshall Hall discovered the reflex function of the spinal cord; how that, when an impression is conveyed along a sensitive nerve to one of the posterior columns of that cord, the resulting stimulus may be "reflected" or turned back through an anterior column and along a motor nerve, and may call muscles into activity without the intervention of volition or consciousness. This seems to me very precisely to define the instantaneous and almost unconscious negative which would leap to the lips of an overworked man of letters on ordinary occasions when his nervous system became suddenly stimulated by the demand for a discourse about some subject outside his usual studies. But when the honour fell unexpectedly upon me of being invited to distribute prizes here to-day to the students of the Medical School of St. Thomas's Hospital I could not consider the occasion ordinary. The profound respect which I feel for your noble profession; my true delight in its progress and advancing achievements; the firm hope I entertain of greater medical and surgical developments to come which will by-and-bye render human life more pleasant and more prolonged, my many friendships among the leading physicians and surgeons of the day, my own private gratitude to the skill and goodness of some among them, and my personal interest in your great and useful foundation of St. Thomas's Hospital—these, with other considerations, suppressed in me that "reflex" and automatic "No" which the shyness of the scholar's study and the dread of apparent presumption on his part must otherwise have enjoined. I felt that it would prove a real and memorable pleasure to me, as well as a singular honour, to speak as a man of books, philosophy, and politics to those who will be the surgeons and physicians of the coming century, if only that I might discharge my individual debt to their order, and might ever so imperfectly prove to them with how much warm sympathy their labours and successes are followed in the sphere of literature and journalism. It is thus and therefore, gentlemen, that I stand before you to-day.

The next step was to learn something as to the extent of the patience with which you are accustomed to permit outsiders to talk to you upon topics whereon the best of them can only possess an "intelligent ignorance." By the kindness of your chief officials I received several elucidatory documents on the matter, and among them an extremely interesting copy of the address delivered in this same place last year by my learned and witty antecessor, Dr. Merry, Rector of Lincoln College. After reading that admirable composition, which said so many things that I would have liked to say to-day, only more brilliantly, my emotions were very much the same as those of Michael Angelo when he was riding out of the gates of Florence with a written commission to construct the Basilica of St. Peter's at Rome. They say that he turned round upon the saddle of his mule and, gazing at the stately and beautiful Duomo rising into the Italian sky behind him, ejaculated mournfully, "Come te non voglio, meglio di te non posso" ("I will not build like you, yet better than you I can never build"). So I say of the reverend rector, who, being public orator for the University of Oxford, playfully regretted that he was not allowed to discourse to you in Latin. I fear it would only seem plagiarism if I also should sigh for permission to speak my mind on this high occasion in a poem or a leading article! He has further anticipated most of the neat classical things I might and would have cited about medicine out of Homer, Plato, and the ancients. He has recounted more than one of my own favourite stories about medical men, while in all he uttered upon the dignity of your calling, its duties, its difficulties, its moral and social exigencies, I should need to borrow from him his gravity, authority, and eminent academical standing to tread with safety in the footsteps of that most excellent lecturer of 1894.

Yet I will not yield to Dr. Merry or to anyone else in admiration of the magnificent record of medicine and surgery in England, or in heartfelt honour for those who have given their lives, and are here and elsewhere preparing to give them, to the pursuit of this, in my judgment, the best, the gentlest, the loftiest, and the purest of the secular crafts which men follow. You, gentlemen, begin by self-devotion and fearless defiance of risks which others dread and shun. Your original choice is brave, your early ambition honest, your first steps hard, your daily work, even if ever so little elevated by enthusiasm and faith, is work that brings help and hope to your fellows and constitutes you the common friends of all. And the really educated medical man who knows himself the accepted servant of science and nature, and the messenger, as far as can be, of Heaven's eternal pity, has moments, we all believe, of rich success and boundless recognition that make his fees the very smallest part of his after-payment in life.

Moreover, you are advancing, like true victors in a march of constantly augmenting conquests, over that strange fascinating waste of twilight and wondering exploration which is called "science." There have been times when it was not particularly honourable to be a medical man. The specimens of medical and surgical practitioners whom we find held up to ridicule in the pages of Molière or in the pictures of Hogarth deserved, as far as can be judged, the pillory of immortal scorn in which their ignorance and pretentiousness have been placed by the genius of satire. Yet there were not wanting, even in times of Thomas Diafoirus, serious and modest searchers after the secrets of healing—men imbued with the dignity and solemnity of their calling; and, indeed, I think we could fill up every single age, from Galen and Avicenna to Ambroise Paré and John Hunter, with the names of truly great practitioners. But your lot, gentlemen, is cast in an epoch of such acceleration of knowledge, such expansion of methods and resources, such ever-increasing power of doing solid good to your kind, that the old satires have all died away. The new age frankly honours and values your vocation, in discharging which you yourselves move forward by rules more and more exact and less empirical. Before an audience so specially intelligent as this it would be presumption for a non-professional man to speak with an air of information about the advance of your science. Nevertheless, a partial interest may attach to what someone from your outer world of patients thinks of your inner world and work as medical men. Living men of sixty years or so belong historically to the present happy reign, and within that reign we can recognise, though lacking your closer observation, what prodigious progress has been accomplished by medicine and surgery, and, I may add, in the science of sanitation. It was one of the surgeons of St. Thomas's Hospital, the illustrious John Simon, F.R.S., who may be said, in conjunction with Mr. Edwin Chadwick, to have actually invented public hygiene. These great benefactors and their able assistants had none of the knowledge which you all, in greater or less degree, now possess about bacilli and bacteria; but by improved drainage, purer water-supply, good paving and scavenging, removal of refuse, and prevention of overcrowding they succeeded in establishing such a difference between clean and unclean places that the way was paved for the fruitful discoveries which followed. Dr. Buchanan, inspecting for the Privy Council eight years after the new decencies began, found death-rates reduced by percentages ranging from 16 to 32. Dr. Snow in 1849 from the well in Golden-square, Dr. Budd in 1857 from typical typhoid fever cases, and Mr. Netten Radcliffe by the light of a limited outbreak at Theydon Bois, helped in establishing the truth that zymotic diseases have their special seeds and grow after their kind, which the experiments of Pasteur, Tyndall, and others came fully to confirm. Hence we outsiders have seen with wonder and with hope the present epoch spring up of the germ, the preventive inoculation, the serum injections and what not of rich research and promise. Nor can even persons only partially informed think of M. Pasteur's superb triumphs over anthrax, splenic fever, the silkworm disease, and perhaps we may add hydrophobia, without their minds passing to the quick genius with which Lister applied the generalisation of these facts to surgical lesions and, under his new system of antiseptic, vastly diminished the anxiety of the operator and the perils of his patient. In this connexion I mention before you for honour the name of

Digitized by Google

my late illustrious friend, Professor Tyndall, since no one outside your own profession wrought more successfully or brilliantly to show the difference between airs and liquids, natural and sterilised. This delicate conflict against our infinitesimal enemies has been carried on with supreme ability by Klein and Koch and many another well-known living benefactor, although there is now I observe a kind of reaction in favour of some of these microscopic beings, since some seem friendly. "The most important fact," said Sir J. Russell Reynolds in his discourse this year before the British Medical Association, "with regard to recent microbiological research is the gradually increasing appreciation of the fact that these lower forms of life exert, not necessarily mischievous, but, indeed, benignant influences on the human body, and that although the mode of their operation is not fully explained they take part in healthy processes, assisting normal functions, nay, indeed, it would seem sometimes producing them and warding off the malign effects of other influences to which we are habitually exposed."

We know already that a man's well-being may depend almost as much upon his leucocytes as upon his domestic relations, or the state of his digestion, or the balance at his banker's. The antitoxin treatment of diphtheria, which was, on the whole, favourably reported on at the recent meeting of the British Medical Association, is another example of the novel and hopeful enterprises which are being pushed into the region of these micro-organisms. Yet it was only at the beginning of this reign that Schwann connected fermentation with the activity of the yeast cell, and not until 1860 that the Academy of Science gave its prize to M. Pasteur for the brilliant essay which swept away all lingering theories of spontaneous generation. And now you have at ever-extending command this vast new region of bacteriology, wherein sunshine and daylight and the wonderful natural forces of life and those that are friendly amongst the microbes fight on the side of your enlarging science and on our behalf against the "pestilence that slayeth in secret." A great authority has declared that "a day will come when in London, in Berlin, in Paris, man will not die of diphtheria, of typhoid, of scarlet fever, of cholera, or of tuberculosis, any more than he dies in these cities to-day of the venom of snakes, or of the tooth of wolves." Perhaps even our invisible enemies contend amid themselves. I noticed with interest a remark of Sir William Broadbent at the meeting of the British Association, when he said: "One virus may be antagonistic to another; an attack of small-pox has often seemed to cure phthisis."

In connexion, moreover, with that promising subject of the antitoxins, such as those for diphtheria and tetanus, there is some promise, be it observed, of injections which will neutralise snake poison. Professor Calmette in France and Professor Fraser of Edinburgh, after patient experiment with snake venom, have apparently succeeded in rendering rabbits, and eventually horses, proof against doses of this 350 times stronger than an ordinarily lethal quantity. The details of the matter are most interesting, but too elaborate for statement here.

The amount of "antivenine" required to immunise a horse is considerable, and it took Professor Fraser some time before he could collect sufficient material to begin on. Having done so, however, he selected a healthy horse and injected it for over four months, by which time it was immune against any amount of venom. The serum obtained from it was then tried and found to be highly satisfactory. It can be desiccated and packed for transmission abroad in a form which will keep. One must have lived in India, where the recorded annual mortality from snake-bites is over 22,000, to appreciate the vast hopefulness of such a remedy against the deadly cobra and murderous krait. What would not be the gratitude and wonder of the Indian peasants if this antivenine should prove a success?

Has anybody given thought in the same connexion to what might be done to rescue the draught cattle and horses of South Africa from the tsetse fly? Whole belts of our growing empire there are cut off from trade by the poison of this tiny plague, which kills all horses, oxen, and donkeys that it stings, yet has no power whatever upon the zebras, buffaloes, and wild beasts of the Veldt. If the blood-serum of these naturally acclimatised and adapted creatures of the same genera, properly applied, could give immunity to South African caravans, millions of money might be saved to the colony.

It would be very presumptuous of me to speak, except from my point of view of a more or less intelligent ignorance, about your refinements in the use of the stethoscope and auscultation; your largely improved surgical and medical armoury; your specula, laryngoscopes, and hypodermic syringes; the tabloids and other highly convenient forms of modern medicines, exquisite appliances of the benign art unknown until later times. Possibly modern surgeons are even a little ahead of physicians in the exciting race, for while we see that the French medical officers cannot prevent the malarial plasmodium from prostrating half the Madagascar expeditionary force, I have read with admiration in a recent discourse of your distinguished chief, Sir William MacCormac, by way of illustration of the increasing effort of modern surgery to provide antiseptic protection in an effective form, that "during our last war in Egypt the organisation was so complete in this respect that not a single case of infective wound disease occurred during the whole campaign." Then, too, we outsiders have heard with wonder how you are coming to use animal extracts in medicine and how you think to reinforce failing human organs with the active principles derived from similar animal organs, as in the case of Dr. Ord's practice and Dr. Lauder Brunton's thymid tablets. If this can be done for myxœdema the jungle fables seem half justified which prescribe lion's flesh to render men brave and the eyes of lynxes to make them keen-sighted. It tends to explain a recipe which I once saw in an old black-letter book styled "Alexis hys Secrets." The prescription was for the prevention or cure of burns and scalds, and it commenced by the ordinance, "Tayke, and powder as small as ye may, a salamander."

But I need not dwell further upon these widening powers and expanding prospects of your noble profession when you can read in the eloquent address with which Sir J. Russell Reynolds opened the recent meeting of the British Medical Association the declaration and the comment which I shall take leave to cite. He began by observing that the great surgeon Sir William Fergusson, who presided over the last London meeting in 1873, might have paused, with all his dauntless courage, to perform an operation which either of his dressers of twenty years ago could be announced to do to-day, and would do without fear or dread, and that Edmund Alexander Parkes, who then delivered the Address in Medicine, would, if he could return to his old haunts, be entirely bewildered and amazed if he found his house physician feeding a patient on sweetbreads or injecting thyroid extract for the cure of myxœdema. And the President of the College went on to observe upon the far greater interest and earnestness which characterise the student of to-day as compared with his predecessor. "Much of this," as he said, "was due to the indulgence of a larger hope. Hidden as still are the great mysteries of life, there yet emerge certain definite facts to be grasped by the mind, to be seen and handled, not only imagined or asserted; and the place of these facts in the economy of Nature, their bearing upon others, and their relation to work yet to follow give a precision and confidence to study that is, comparatively speaking, of modern growth. There was plenty of assertion and show of knowledge in the past; but even the teachers did not believe the half of what they taught, nor comprehend the half of their sage pronouncings. Nature has, as it were, taken man more into her confidence and daily reveals so much, even while concealing more, that the learner stands firmly on the ground he has gained, instead of trembling on a quagmire the length, and breadth, and depth of which he could not see and did not dare much to imagine or investigate. He felt sure of little then but of his own and his teacher's ignorance, but now he grasps much that is ascertained truth and such as can be seen, shown, measured, and recorded with perfect accuracy."

But let me take permission to tell you that what fill my own heart most with thankfulness and cause me chiefly to congratulate you on these new days of therapeutic science are the benign, the blessed discovery and the now almost universal employment of anæsthetics. If you look into the history of that happy revolution you will be warned against depreciating fresh ideas by noticing how sadly slow men are to take the hints which Nature gives to them of her very choicest treasures of resource. *Why* did not anyone act upon what Sir Humphrey Davy had so long before learned and imparted about the properties of nitrous oxide? The key was already there, but not until many years afterwards did an almost casual hand (that of an American dentist) fit it

Digitized by Google

into the golden door behind which sate waiting an Angel of pity kinder and more powerful than any Arabian fairy suddenly revealed in her divine beauty and bountifulness to any prince or magician of the "Thousand and One Nights." Is there anything in human history which more sternly teaches that man must win every boon of Nature by his own ceaseless striving than that this simple chemical and physiological secret of chloroform should have lurked so strangely long in its easy formula, undeciphered, through all those waiting generations when pain was an omnipresent tyrant whom science could not control, and the operating room a torture chamber dreaded almost as much by the surgeon as by the sufferer? Think of those gallant sailors of Nelson at Trafalgar, whose bleeding stumps, in the gloom of the orlop deck, were plunged into hot pitch to stay the hæmorrhage. One would almost expect that, for pity of such brave men and for the sake of the countless tender women and children who, age after age, so hopelessly endured, Telesphorus, the God of Healing, or Nature herself, would have burst their iron law of impassive silence, and, as Helen did in the "Odyssey" for the sorely tried Greeks, have poured this nepenthe into the bitter cup of mortal life. I can remember the poetess Eliza Cook, whom as a boy I knew, when chloroform was still unknown, writing how—

> "Lips that blench not in the reeling strife
> Turn silent and white from the surgeon's knife."

Not until 1847, although Davy had been so near the revelation in 1839, did the anæsthetic age commence, giving to your art a sure control of anguish; to its boldest practice confidence, quiet, and leisure; and to those who have to lie under that knife a sweet and complete oblivion. I have myself known what it is to pass, fearless of the kind steel, into that world of black velvet tranquility of which your magic drugs now keep the gate, and to awake as good as healed, grateful beyond words for the soft spell of enchanted peace and the sure and faithful skill. You will all agree, I am confident, with an extract which I have taken from the excellent paper upon "Medicine and Surgery" contributed to a work called the "Reign of Victoria" by Mr. Robert Brudenell Carter. He writes: "The use of anæsthetics has changed the whole aspect of surgery. Prior to 1847 operations were few in number and almost limited to the amputation of limbs, the removal of cancerous and other tumours, the resection of a few of the larger joints, cutting for stone, and the ligature of main arteries for aneurysm. The pain suffered by patients was so horrible as to tax severely the endurance of the bravest and strongest, and to depress seriously, and ofttimes beyond recall, the powers of life. Death from 'shock' was by no means uncommon, the patient sinking in a few hours from the actual suffering which he had undergone. The writer well remembers, as a medical student, turning sick and faint at the agonies which he was called upon to witness; and it was a point of honour in those days with operators to abbreviate such agonies as much as possible and to cultivate mere speed in operating, as the highest and most valuable form of dexterity. Nothing was attempted which could not be done quickly, and an amputation in the hands of a practised surgeon was forced to assume almost the appearance of a feat of legerdemain. For the separation of the lower limb above the knee—of course, not including dressing—twenty seconds have been known to suffice, while forty seconds was regarded as a period of time which no one was justified in exceeding. When anæsthetics were employed it came to surgeons as a kind of revelation that they need no longer be in a hurry.

Thus in 1847 Simpson and his coadjutors put into your hands a chain to bind at will the demon of pain, and in 1865 Lister at the Glasgow Infirmary by his antiseptic method inaugurated your grand conquest of pyæmia and septicæmia, and that ancient standing terror of the "hospital gangrene."

I will not venture to pass from such broad and common grounds of congratulation to speak before my present audience of the detailed triumphs of latter-day surgery; what you have lately learned in this your "Palace of pain" from the splendid successes of your chiefs, and will afterwards beneficently and boldly practise in regard to ovarian tumours, eye and throat diseases, and the rest. Moreover, while ordinary conquerors must reckon the dimensions of their victories by the numbers of the slaughtered, your glorious campaign computes the magnitude of its triumph by lives saved or prolonged, by pains and injuries abolished, and by the uses and pleasures of human existence restored. One of the high authorities already quoted has furnished a calculation of the salvage of life effected even during the early years of the present reign by the commencing improvements in preventive and curative medicine. In the five years from 1838 to 1842 London, with an average population of 1,840,865 persons, had an average annual mortality of 2557 in every 100,000. In the five years from 1880 to 1884 the average metropolitan population was 3,894,261, and the average annual death-rate 2101 in each 100,000. A calculation will show that these figures represent a saving or prolonging of lives during that lustrum to the number of 96,640. The mean annual death-rate has now been reduced to a point lower than shown in these. It was 22·16 per 1000 for England and Wales at the commencement of the reign, and it is to-day better than 19·0 per 1000, while in Her Majesty's army and navy the diminution of mortality apart from deaths from warfare has proved even more remarkable, and in India, where we used to lose 69 per 1000 yearly, this has been reduced to 16 per 1000.

I have met in this great hospital gentle and graceful presences which lead me to allude to one more great and happy change among many that has come upon your profession—I mean the education and employment of professional female nurses. A great physician once said in my hearing "that the three most sovereign medicines he knew were hot water, fresh air, and good nursing." In your fathers' day, gentlemen, we had no good nursing; we had Mrs. Gamp and Mrs. Betsy Prig, or else heavy-handed and heavy-footed male attendants, very different in mind and manner and influence from the lightly moving and softly speaking woman whose carefulness—intelligent, pitiful, but tranquil, trained, and governed—now smooths every sick-pillow and carries out faithfully and fearlessly the ordinances of the doctor. I do not know whether you, the surgeons and physicians, or we, your patients in *posse* or *esse*, are most to be felicitated upon this admirable revolution in the hospital ward and the sick-room. There is no doubt that it was primarily due to the example of that most compassionate and noble-hearted woman, Florence Nightingale, who went, at the head of a band of nurses, many of good birth, to the Crimean War, and by demonstrating there and afterwards the immense advantages of skilled and high-class nursing gave to her age the blessing of this modern system, and to her sex a new, a suitable, and a most honourable vocation. You have greeted the name of Miss Nightingale with instant and hearty applause. That generous tribute to her, who in her old age and retirement is even now the centre of so much silent national affection, encourages me to remember that I am, after all, poet by nature and lecturer only by accident, and that in those dark hours of the Crimean War I wrote certain verses, which are perhaps brief enough to be on this occasion acceptable. If I am so bold as to recall them from their unprinted oblivion it is because what they express of admiration and gratitude is applicable in a great degree to every good and dutiful nurse, here and elsewhere, who loyally discharges this new and most womanly function.

[The lecturer then recited the subjoined lines:]

> "If on this verse of mine
> Those eyes shall ever shine
> Whereto sore-wounded men have looked for life,
> Think not that, for a rhyme,
> Nor yet to suit the time,
> I name thy name, best victress in the strife;
> But let it serve to say
> That when we kneel to pray
> Prayers rise for thee thine ear can never know,
> And that thy gentle deed
> For Heaven and for our need
> Is in all hearts as deep as love can go.
>
> "'Tis good that thy name springs
> From two of earth's fair things—
> A stately city and a sweet-voiced bird.
> 'Tis well that in all homes
> Where thy kind story comes,
> And brave eyes fill, that pleasant sounds be heard.
> Oh, voice! in night of fear,
> Like night's bird's—sweet to hear;
> Oh, strong heart! set like city on a hill:
> Ah, watcher! worn and pale,
> Dear Florence Nightingale,
> We give thee thanks for thy good work and will.
> England is glad of thee;
> Christ, for thy charity,
> Take thee to joy when heart and hand are still."

This topic tempts me to glance at another closely connected with it, which has always had my earnest interest and support—I mean the movement so excellently instituted and so successfully carried out by my most noble friend the Marchioness of Dufferin and Ava for the supply of English

Digitized by Google

female doctors to India. In that country, by reason of its peculiar institutions, we are secure from any controversial questions as to the fitness of women for your profession. The customs of the *purdah* absolutely forbid the high-caste Indian ladies to avail themselves of male European skill. I was dining once in Jeypore at the table of Surgeon-Major Hendley, the able and trusted friend of the Maharajah, when a message came that the chief queen had been taken ill, and begged the advice of the British hakeem. He went, and, on returning, told us that although for seventeen years a familiar visitor of the palace, and the private adviser in many matters of the Rajpoot Prince, he had been obliged to suffer his head to be enveloped in a silken bag, and so equipped had been led into the zenana, where he had felt the pulse of her Highness and had examined her with the stethoscope, without seeing an atom more of his patient than a glimpse of one jewelled slipper through the strings of the bag. Here is a medical and surgical field, therefore, wide and unfilled, which might absorb any amount of feminine ability and devotion—if only proper public support be given—and I ardently entreat your countenance and assistance for it in the course of that professional influence to which I well know many among you are destined to rise.

I shall also take courage, since your kind attentiveness proves you convinced of the sincerity of my interest in your profession, to touch upon yet another topic, bristling, I know, with dangers for outside observers. I have read, in one of the able disquisitions already quoted, a paragraph dwelling upon Harvey's grand discovery of the circulation of the blood, where, after mentioning that that splendid revelation was the result of experiments performed upon living animals, the talented writer—a great living practitioner—goes on to say: "The whole fabric of modern medicine, the whole difference between the prospects of a sick man to-day and his prospects 200 years ago, rests absolutely upon vivisection." I shall not venture, in presence of knowledge and experience so much vaster and riper than mine can be upon such a matter, to dispute or qualify that assertion; nor shall I as an individual take on myself to deny to conscientious science, as many persons deny whose motives and arguments I most deeply respect, the right claimed to pursue essential experiments at the cost of the pain and death of innocent creatures. If to give my own life under torture would certainly lead to the saving of very many other lives, I should hate and scorn myself if I had not the will so to die; and as between men and beasts I suppose it is true that we are "more than many sparrows." But my private feeling, founded upon an ever-growing sympathy for the lower animals, an ever-increasing wonder at their gifts and capacities, and an ever-deepening sense of our human responsibility to them, was expressed in a phrase which I know was extravagant, used by me to a famous contemporary surgeon who said: "What, Sir Edwin, may I not vivisect a cat to save the life of a bishop?" And I replied: "Yes, Sir Henry, on condition that you afterwards give the cat a public funeral in Westminster Abbey as a benefactor to the Church and to humanity." Of course that was paradox, but I am persuaded that all of you will understand me, and many will agree with me, when I declare that this solemn right to succour pain by inflicting pain has its best foundation upon an immense reluctance to adopt such a necessity, an anxious economy of anguish in the act; in fine, a feeling not of the heedless experimentalist but of the priest sacrificing victims for propitiation. I say again that I disclaim any pretention to teach mercy to you whose vocation has mercy for its watchword. I will not share with my age the fruit of patient physiological researches and then hastily reproach those who have laboriously acquired them for the general good. But as regards my own sentiments, that which chiefly led me to write "The Light of Asia" was the boundless and beautiful tenderness of the Buddhist religion towards the lower animals, whose lives are so mysteriously related to our own, whose lot is so largely at our disposal, and who are to us much as we human beings are to that invisible Almighty Power at the feet of which we have sometimes little cause to wonder when we ask in vain for pity and clemency. Therefore I will be bold enough to-day to put in this humble plea for the dumb martyrs of vivisection, that they may be as few as possible, as mercifully dealt with as possible, and that it be held by the inner *religio medici* which every true doctor cannot but possess and profess, that the meanest living thing so sentenced to suffer and to perish for mankind derives from its very doom a certain enhanced regard and a special consideration to which the conscience and honour of him who is a gentleman as well as a doctor will never be insensible.

But I am not here, as I before remarked, to inculcate reverence for all forms of existence and tenderness towards all suffering upon those whose glorious vocation it is to be merciful, sympathetic, and conscientious. Very quickly must the chivalrous aspect of a good doctor's life lay hold of him, as is sufficiently shown by a memorial which I have observed in your chapel. A tablet there records how your fellow-student in this medical school gave up his young life in the desire to save that of some obscure and humble patient. To my thinking no cathedral, no Chapel of St. George at Windsor or of Henry VII. at Westminster, no shrine or temple or sanctuary anywhere, can contain an epitaph more touching to peruse, more nobly commemorative of the dead, more splendidly honourable to the institution which trained him, and to-day trains, I doubt not, many like him. We have all of us lately read, too, of the heroism displayed by Surgeon-Captain Whitchurch in the fighting at Chitral on the Indian frontier, heroism justly rewarded by Her Majesty, and such as casts a lustre upon the whole profession. Well, gentlemen, having your walls enriched with such an example, and so many similar proofs existing of the chivalry of the profession, it is not possible, I think, that your studies and experiences should lead you permanently to the materialistic view of life. You know, or will know, far too much to believe that science can ever know all. While the wonderful advances which have been made in locating brain disease, and analysing and controlling the functions of muscle, organ, and nerve, appear to recommend now and again the easy theory that life, like heat, is only a "mode of motion," the perpetual mystery will still rebuke it of that bridge, never to be traversed by anatomist or metaphysician, whereby molecular movement and intellectual consciousness cross and recross in correlations. You will find yourselves admiring, emulating by your disdain of danger in face of duty, the illogical but magnificent transcendental philosophy of those your comrades, whose secret souls knew the immense wisdom of that verse, "He that seeketh to save his life shall lose it; and he who loseth his life, for my sake and the gospel's—the same shall save it." What gospel, gentlemen? Why, surely that which we have called, and may rightfully call, the *religio medici*; the good tidings to humanity of a science which, itself moving in the midst of constant personal peril, yet treats every human life as unspeakably precious; which succours and sustains all alike; which asks as little as the air we breathe, or the water we drink, whether we suffer by our own faults or otherwise, but always dispassionately pities and always impartially assists; which, all too grudgingly recognised by those who distribute the honours and emoluments of the State, and poorly recompensed, I fear, for the most part with the goods of this world, has generosities undreamed of towards the poor, maintains a professional honour rarely, if ever, stained, and shares with the faithful minister of religion and the honest lawyer the utter and ultimate confidences of those who have recourse to it. It is clear that the members of such a profession must in their farthest and deepest thinking be of the secret view that the diphtheritic bacillus or the foeman's bullet can do no final and far-reaching hurt to the real life of a good man. "If worms and maggots end us," wrote my old friend Walt Whitman, "then alarum, for we are betrayed." We are not betrayed! Nature—which seems to waste so many existences—like you, really disregards and neglects none; like you, she encourages and helps, by the instinct of self-preservation, every single life to live itself out unto the utmost, for reasons which we can partly divine when we see Sir Isaac Newton born a puny seven months' child, and Nelson's heroic spirit lodged in a feeble and diminutive body. I salute you, therefore, gentlemen of St. Thomas's Medical School, as the young reserves of that army whose victories are the triumphs of all mankind and whose enemies are all men's enemies. I know—I have paternal reason to know—that the labours of your educational preparation grow harder and harder and that a good doctor must nowadays be chemist, physiologist, botanist, mechanician, and many things besides. But be sure your credit augments with your pains and your acquirements, and deign to receive to-day in this address—the imperfections of which your indulgent courtesy must forgive—a proof of the sincere interest which Literature takes in your

Digitized by Google

careers, and of the perfect goodwill with which it hears of all your successes and notes the new and nobler status of your great profession.

An Address
ON
OUR PROFESSION, OUR PATIENTS, OUR PUBLIC, AND OUR PRESS.

Delivered at Guy's Hospital on Oct. 1st, 1895,

BY G. H. DE'ATH, L.R.C.P. LOND, M.R.C.S. ENG.,
CORONER FOR THE WINSLOW DIVISION OF BUCKINGHAMSHIRE, MEDICAL OFFICER OF HEALTH OF THE BUCKINGHAM RURAL AND URBAN DISTRICTS, ETC.

GENTLEMEN,—It may seem to many, but I hope not to all, to be something like a waste of time to consider the relationships between the profession, the press, and the public. Public support is fascinating, but fickle. In times of war soldiers are the pets of the people (and, however strange it may sound, I include all classes in that term), but in times of peace "doctors" are the fashionable craze. Society, "forsaking even military men," throws her charms to great wealth, successful humbug, the drama, and the medical profession. We should warn ourselves against judging by appearances, especially those which are nearly always deceptive. Let me take a somewhat out-of-the-way instance to show what I mean. It is often said, "He does not know his own mind." Of course not. No one knows his own mind. It is one of life's purest pleasures to make its acquaintance. We know the existence of our own minds and we infer the existence of mind in others. It is, indeed, delightful to find out, by thinking, writing, or speaking, what is "in our minds." It is a useful habit to acquire because it cultivates the rarest and best characteristic of a medical man—namely, observation. I submit it is necessary for us to see where we are and to see what we are doing, but how rarely we do see. We look, but we do not see? We do not see our work, or ourselves, or how others see us. Again, look over a landscape of undulating country, with its varied forms of green, its play of colours lit with the great, grand, golden glory of the sun. What do we see? Is the beauty of nature only the expression of successful cruelty? Again, turn for a moment and ask yourselves if the apparent calm of humanity is only what covers, but does not really conceal, the constant—and may I add cruel—struggle for existence? Is it true nowadays, when every man poses as the friend of all men, that "man's inhumanity to man makes countless thousands mourn"? Now you will ask me, What are you driving at? Simply that we must beware of our relationship to the public and see to it that it is a true and honourable position for us to occupy; simply that we should learn, not merely to look, but to see men and women and all things as they actually are, and not only as they appear to be, for all "things are not what they seem," and no man and no thing is what he or it appears to be. So, indeed, and too often, the appearance of hypocrisy or of honesty in our lives resembles the appearance of nature where peace is but war, and beauty but hidden ugliness. We do not only require lucidity in our view of the outside world, but lucidity of expression in the use of medical terms. Surely we must learn to see men and their maladies as they are. We need not pretend that we do not value public esteem and confidence, but what steps do we take to deserve either when we hide our ignorance or our knowledge under loose terms? The fashion has not yet died out of labeling as "hysterical" any group of symptoms which are inexplicable on known physiological grounds, and this at a time when we do not know with certainty either the real effect of a poultice on the skin or the functions of the liver. The modern student, especially if recently qualified, regards as "neurotic" all the symptoms which do not come within the range either of his reason or his remedies. How do too many treat the conditions which they call "neurotic" or "hypochondriacal"—meaningless epithets that are used either with that haughtiness which is a proof of ignorance or with that pity which is only another form of the same narrow-minded contempt? First of all they deny the existence of the malady, then they say there is nothing the matter, and when the patient recovers under the treatment of a man who is a physician without being a fool they then sneer at the successful colleague as a man who humbugs his patients.

A section of the profession, notwithstanding all its post-prandial sentiment, is jealous of success. Surely it is utter nonsense, because it is absolutely unreasonable and deplorably unscientific, for a person to be ill and well in the ordinary senses of the terms, or that anyone (apart from the very definite condition of malingering) can "imagine himself ill." People who are ill are ill even if we do not understand the illness, and even if we cannot treat it. Let me give one more instance, because it is one which more obviously affects our relationship to the public and our patients. I refer to our unfortunate habit of separating "functional" from "organic" maladies. Function is the expression of organic change, and functional disorder is inconceivable without organic disturbance and change; and the latter is not the least, but the most, important factor, even if unrecognised, in those disturbances of health so stupidly called "only functional." It is more conceivable to think of organic change without functional disturbance than of functional disturbance without organic change. Why is all this? Why do we talk thus to the public and to our patients and to ourselves? Why do we rely on appearances and vague terms? Why do we thus lose, or deserve to lose, public confidence? Because in hospital life and training we fail to note the value of seeing life as it is, people as they are, or the true meaning of terms. In hospitals we learn about disease, but in practice we have to treat a person with an illness. Large numbers of cases (or diseases occurring in persons) pass under our observation in hospital life, but we only see the diseases, not the persons; not only that, but both the person and the malady are removed from the conditions which would otherwise act on both; and, in addition, the greater part of our hospital life is spent in studying just those maladies which, however important as types, are least often seen in general practice. In hospitals we see, or rather look at, others treating an illness in a person, but in practice we ourselves have to treat a person with an illness. We rarely in the hospital see those deviations from what we call health which we have to treat in general practice. Thus, before we get into practice we do not see our work as it really is, but only as it appears to be. Our teachers, to whom no one is or ought to be more grateful than I am, are men who are what they are because they have been successful in hospital practice or distinguished for successful industry, and these men pass, and perhaps rightly, from the hospital to Harley-street, but they see little or nothing of ordinary general practice or the "cases" which we as general practitioners have to treat. They teach hospitalism and practise it. Men who have, therefore, to deal with patients or the public—that is to say, start in practice—are lost to some extent, have no power (because they have not the knowledge which is power) to conduct a case, know not how to treat their patients or their patients' friends, and cannot even behave themselves in a sick-room—in fact, many men only go into a sick room for the first time after they are qualified. We must remember that the proper study for the medical man, at all events, is man. A hospital is no more and no less the place to learn the diseases of mankind, so far as the relationship between patients and medical men are concerned, than are zoological gardens the proper places in which to learn or to study the natural habits of animals. Much can be found out at either place, but as at zoological gardens we see animals under unusual or unnatural conditions, so in hospitals we see illnesses and people separated from the conditions by which they are both surrounded when we as medical men have to treat them. These considerations affect the public as a body and the public individually—as our patients, as we call them. I would speak of the latter first.

A patient expects that his medical man should be something more than a mere medicine man, that he should be more than a detective to discover some pathological flaw in his health, and something more than an accountant to bring out the balance of a diagnosis from the complicated accounts of his symptoms. The public also expect much, and perhaps too much, from its public professional men in the protection of health. To us, of course, health is only a relative term, but to the public it is an attainable reality. I have never seen a case of health, and I should like to see a really healthy man, woman, or child, and it is, by-the-bye, in the detection of the insignificant departures from an indefinite standard that the skill of the medical man lies. We do not treat the

Digitized by Google

public fairly in the matter of health. For instance, we say "disinfect," but there is no reliable standard either of disinfection or a disinfectant. Again, people want to know what to do in cases of illness, emergencies, and during epidemics. What do we do? What does the profession do? It supplies the public with scientific beef-tea, not in tins, but in lectures; it attempts to boil down the hard bones of science to suit the digestion of the public intellect; it floods the press not only with watery but adulterated solutions of science, while essences of surgical treatment and tabloids of medical knowledge are manufactured wholesale for general consumption. We want to appear to know and to make others like unto us. This is what is called and appears as the popularisation of knowledge, but in reality it is the prostitution of science. No doubt a knowledge of the laws of health can be taught—the means by which homes should be kept clean and filth removed from the person and the house, the advantages of light, air, and the diet of children—but amateur medicine and surgery are less reliable than the professional articles. We think we are to teach our patients and the public what we know; if so, they must learn as we do. If our methods of teaching the public are right, then our own methods of learning are both wrong and useless. We allow the public to think we can dispense clinical therapeutics for them. People demand the knowledge how to treat illness, and we supply a lecture or a course of lectures. I have often protested, and I again beg to protest, against such "apparent teaching," against the policy of sprinkling the community, by means of a more or less oratorical pepper-box, with tit-bits of knowledge, whether pathological, physiological, obstetric, or hygienic. There are no such short cuts to knowledge. The appearance is not the reality, and as we learn so we should teach, and not otherwise. A desire to know is admirable, but the public are nowadays too inquisitive about illness. Our national manners show a deplorable lack of taste and good feeling in the presence of illness. If a man consults his lawyer he does not find all his friends asking him what is his business or why did he seek legal advice. Let such a man, however, consult his medical adviser, and at once all his friends and acquaintances—sometimes perhaps out of kindness, but more often out of curiosity, or, in the case of a celebrity, out of a feeling of snobbery—at once rush to know what his business was and why he sought medical advice. It is sad to have to add that even the medical man himself is asked concerning the case, and it is a shameful thing to have to admit that the information is often granted. The near relations of a patient may be told the nature of an illness, but without the express sanction of the patient or his closest relations no medical man has any right to make any sort of communication to anyone else—not even, I submit, to the medical press. The so-called upper classes, or certain sections, have, let us not forget, brought advertisement to an art. It is time we did something to protect the privacy of the home, especially of the sick-room. To publish clinical details, or to throw the sop of a temperature chart to the gossiping wolves, and to make the sick-room a market for advertising, are practices which are too disgusting and far too common. We all know the twaddle which is talked in the profession about advertising, especially by the sort of man who, swearing he would never advertise, advertised. Our medical press bids fair to become the mouthpiece of the would-be successful traders and of the professional Pecksniffs and Chadbands. For instance, the contribution of cases is intended to advance knowledge, not to puff practitioners. We must look up to our press, but it should represent all that is most dignified and all that is best. Look at the view which is taken by the medical press—and, of course, I am only speaking of some papers—on any subject of general interest, such as vaccination. The coarsest, the rudest, and the most insulting language is considered too good for those who, although supported by men of science and undoubted honour, feel a conscientious objection to compulsory vaccination. Dictation is not dignity, and the policy of kicking your opponents to death should hardly be the characteristic of the wonderful and advanced medical knowledge of the nineteenth century. We must bear in mind that the lay press is ever struggling to get personal details. It is, I submit, a national calamity to see the honour, purity, and responsibility of the press stained, and even in some instances washed away, by the muddy waters of competition. The necessity for paragraphs begets inaccuracy, and belief in the papers is becoming a sure sign of credulity. It is sad, indeed, to see the reckless manner in which that pompous person, "Our Own Correspondent," not only endangers the peace of nations by his highly-coloured and self-imagined crises, but violates the privacy of home life by the publication of details of illness which are generally inaccurate and always inexcusable.

We as a profession must not worship the golden calf of the "Press" too much. From what I see and hear in London, not only the press, but the profession is giving way before the rising and surging waves of competition. I may point out that, although some say competition creates commerce, yet others say it curses it. Must we, however, use such an argument? We must, I fear, if it is true that men who ought to know better and who occupy high positions are not ashamed to steal other men's patients, or to be consultants at one part of the day, physicians another, surgeons another, specialists another, general practitioners another, while all the day long they violate those rules of professional honour to which they do homage only with their lips and not with their lives. These are the men who undermine confidence with "all the kind mendacity of hints," or with a silence more suggestive than speech. When people ask for "another opinion," what they want oftentimes is a "different opinion," and they very often get it, for how many men allow themselves to be privately interviewed by friends and receive fees for such interviews when the conversation turns on "the recent consultation"? These are the men who undermine our press and our patients and force so many of the public to look upon us as money-grubbing humbugs; these are the men who get practice by a "swagger turn-out," by grand-looking houses startlingly painted, by large parties, by gorgeously dressed wives, or by pandering to the bare-faced snobbery of modern society. We must not imitate the methods by which sycophants succeed. We should value public confidence, but we should also deserve it; we should wish for respect, but we should not get it under false pretences. All the world is filled with loud praises as to the advancements in the prevention and treatment of suffering, but novelties are not necessarily improvements, as revolutions are not always reforms, or reforms always revolutions. The light which competition in the press throws into the privacy of the home also finds its way into the laboratory, and the discovery of yesterday is trumpeted as the mark of an epoch. We are thus apt to follow fashions and fads rather than facts. I well remember only about ten years ago, when I had the great privilege of being a student at Guy's Hospital (and I think every medical man should be a medical student all his life), that the profession was suffering from a very acute attack of the "spray." I know one distinguished surgeon who was almost "cut" by his colleagues for not using it. How different now! The profession is now suffering from convulsive attacks of bacteriology. When I left Guy's Hospital the spray ruled surgery, now we all worship germs. In the interests of truth we should appreciate and not exaggerate the relative value of all parts of science. I will only simply allude to "the importance of serum therapeutics," or of the policy of quieting the pathological Paul by extracts from the immunised Peter. Every problem is discussed in the press, and, owing to the habit of pseudo-philosophical generalisation from insignificant details which now characterises modern journalism, the public and our patients are misled.

In these days when the fierce light of publicity beats around a test-tube we must not so quickly take the public into our confidence, especially in the press. Our duty is to look for the truth, not to encourage competition. Our patients are led to think they know so much, and, therefore, when an illness arises they now make the diagnosis and decide on the treatment and the proper specialist to consult. The first question a lady asks when she hears her servant has got rheumatic fever is, "Can she take salicylate?" We know very little, but the public knows less. People now have one medical man for every organ, and I know a lady who consults one man for her eyes, another for her throat, another for her "chest," another for her menstrual troubles, and she herself decides "what is wrong," and then asks me to reconcile the contradictory pieces of advice which she gets from "her London doctors." The false relationships of our public, our press, and our patients to our profession are our own fault. Let us think less of our successes and more of our failures, less of the possible glory of the future and more of the darkness of the present, less of our "modern advances" and more of our modern helplessness, less of the possibilities of science and more of its simplest theories. Let us simply do what is right, and not

Digitized by Google

ostentatiously act as if we knew so much more than we do. Our knowledge is vast, but our ignorance is vaster. Those who have to treat people who are "ill" should study those who are "well." We should value character more than a certificate, and a real success more than an apparent victory. We should be as men treating other men, not as hospitalised beings treating patients. In all our relationships we should remember that kindness, gentleness, and sympathy add to the true value of skill, and that, though the powers of the head are great, the powers of the heart are greater. We can do much by our abilities, but more by our affections, and, although we now have "to live in wearied hope," yet it is not the possible only, but the perfect, we should live for, ever bearing in mind that "greatness is to take the small things of life and walk grandly among them."

An Address
ON
THE EXAMINATION SYSTEM.

Delivered at the Opening of the Session of the Liverpool Medical College, on Tuesday, Oct. 1st.

BY JONATHAN HUTCHINSON, F.R.C.S. ENG., F.R.S.,
EMERITUS PROFESSOR OF SURGERY IN THE LONDON HOSPITAL MEDICAL SCHOOL.

MY LORD DERBY, LADIES AND GENTLEMEN,—In searching round for some topic which should prove of general interest on the present occasion I have hit upon that of examinations. It is one which concerns us all. We have all of us been examined, most of us expect to be examined again, some of us are examiners now and others will be in the future, and, finally, a few of us are ex-examiners looking back upon our own careers and reflecting with much interest upon the whole machinery of modern education, of which examinations form such a prominent part. I am thinking not solely of our professional education, but am venturing for the moment to glance over a wider field. Examinations are the order of the day, and without much regard of sex or station in life we now see the youth of the whole community offer itself as so much subject-matter for the examiner's scrutiny. The motives for this vary in different cases. With many it is the necessity of obtaining a certificate or diploma essential to success in life, with others merely a desire to be honourably distinguished, and with yet others a conformity with custom and an unwillingness to be in any sense left behind. Various, however, as may have been the motives which have drawn students to the examination room, on one point there will have been uniformity, and it is most important. It is this, that the scope of the examination in prospect has been of all importance in determining that of the previous course of study. "This I shall want; that I shall not be asked," has been the ever-present thought in the selection of subjects for reading and thought. Whatever was deemed not likely to be asked for has been ruthlessly put aside, whatever its intrinsic interest. The demands of the examiner set the pace of study, and the breadth of the examination determines the narrowness, or otherwise, of the student's education. Such being the facts, and the probability being that they will increase in cogency as years go on, it is obviously of the utmost importance to the community that careful consideration should be given to the perfecting of our examination system. It may be a hindrance to the spread of knowledge and the development of the mental powers, or it may, if carefully managed, become a powerful aid to both.

The aim of sound education should be to convey to the coming generation as much as possible of the knowledge already acquired by its predecessors, and in doing this to still leave the faculties untrammelled and the memory not overburdened. The teacher, whilst seeking to create and to satisfy the appetite for knowledge, must above all things be on his guard lest his well-intentioned endeavours may repress it and cause disgust. I fear it is not very likely that pass or pluck examinations can ever be made to do much to foster the love of knowledge. Here and there it may by chance happen that a mind is led to see the attractiveness of some subject which would have escaped his attention had it not thus been forced upon him, just as a sportsman may see the beauty of a wild which he would never have visited but in pursuit of game. In the main, however, it is all the other way, and the fag of preparation and the innate dislike of giving reasons on compulsion create distaste rather than otherwise for the subjects concerned. Against this—it is to be feared the natural result of compulsory examinations—it is wise to take all possible precautions. Examinations should be made as little distasteful as possible. To this end it is essential, in the first place, that the element of uncertainty should as far as possible be eliminated. The candidate ought to feel throughout his studies that in presenting himself to an examiner he does that which is equivalent to placing himself on a weighing-machine, and that the verdict recorded will be in exact relation to his deserts. In proportion as the hope is indulged that success may be attained by good luck, will the thoroughness of study be neglected; and just as it may be possible to suspect that the mood of the examiner, the complexity of a question, or some other accidental circumstance may have influenced the result, will be the disappointment and vexation of a pluck. These considerations bring us at once face to face with details. It has been, I believe, the steady tendency of all examination boards to dispense with personal contact between the examiner and the examined, to trust more and more to written questions and answers. To take as instance our own College of Surgeons, the time is not so very long ago when Sir Astley Cooper and a few of his compeers met together after dinner and in a very short space of time, and with very little formality indeed, decided the fates of a batch of candidates. If a student were a man of gentlemanly bearing, if he had studied at the proper school and did not display gross ignorance, he was in no sort of danger. The examiner might ask his name and place of birth, and possibly send a kind message to his father or uncle. All this has been changed now, and so much for the better that a feeling akin to reluctance arises in asking you to entertain the question as to whether further improvements are possible. A large part of the examination is now in writing; it is divided into various departments and occupies probably as many quarters of an hour as the old one did minutes. To be personally known to an examiner is possibly now a disadvantage rather than otherwise, and the responsibility for the result is now shared by a dozen or more of conscientious men acting to a large extent in independence of each other, but never singly. Yet, in spite of these improvements, we still hear complaints—sometimes loud ones, and coming from those who have a right to make them—that the scales of the College do not always weigh correctly. A man may be rejected who was the pride of his teachers, and one may be passed whom they much mistrusted.

That I may avoid the ungracious position of appearing as the critic of a special institution, and at the same time that I may escape the necessity for repetition, I will now venture some general suggestions applicable to all examinations. The personal element, that of the examiner, should be eliminated as far as possible. To this end *vivâ-voce* examinations should as far as practicable be avoided. I have heard a self-confident examiner allege that he could tell better what was in a man in five minutes' conversation than by reading any number of his written papers, and I did not doubt that he thought so. This judgment of men, as it were, by personal inspection is often most fallacious, and should be permitted only with the utmost circumspection. Most certainly the impression so formed by any single examiner, or any two associated examiners, ought never to be permitted to override that of their colleagues. In other words, the result of the examination ought always to be determined by the sum of the marks gained, and no rejection should take place in consequence solely of the adverse vote of a single table. This applies to all departments of the examination, but with special emphasis to the *vivâ-voce*, in which no individual examiner ought to possess the power of rejection. A candidate may be at great disadvantage in the *vivâ-voce*, especially in the hands of an examiner who thinks it his duty to pin him to some subject in which he appears weak. The dawning perception of the possibility of rejection may deprive a good man of his resources, and ensure for him a wholly undeserved fate. Another great objection to *vivâ-voce* examination is that the decision must be recorded hurriedly, on the spur of the moment, and that there remain no data in evidence to which to recur. Few indeed are the subjects in which a candidate is not mos

Digitized by Google

likely to do himself justice (whether to his advantage or otherwise) in a quiet half-hour with pens and ink. It by no means follows that the disuse of the *vivâ-voce* would throw us back wholly on set verbal questions. There remains the extensive field of objective examination. Under this head we have the identification of specimens and the use of the microscope and of chemical tests, and the diagnosis of disease in the living patient. This kind of examination it is which conduces most of all to sound, matter-of-fact, objective teaching. It is, perhaps, the most important of all modes, and is one which in the future is destined to receive more and more attention. Although it may be admitted that the diagnosis of disease in patients can never be suitably done excepting in the presence and under the supervision of an examiner, yet it is better that the latter should not interfere by question or suggestion, and that the candidate should be permitted at his leisure to write out the opinion which he has formed.

We come next to the consideration of papers and of paper setting. Here I have an innovation to suggest. It is that examiners should not be allowed to extemporise their questions, but should be furnished with lists of approved ones out of which to select. It is impossible to deny that of those now set many are ill expressed and some wholly unsuitable. It is no legitimate part of an examination to take the candidate by surprise or confound him with the unexpected. Nor should half of the time allowed be taken up in the effort to understand what the terms of the question are intended to mean. Yet obscurities of this kind are inevitable under the present scheme of question setting, which involves the preparation of them by men under much pressure of other engagements and with but little time at their disposal. Questions suitable for examination purposes should be devised at leisure and expressed in the clearest possible language. Under this plan each separate examination should have its own catechism of questions, to which the examiner should be restricted. Of this a revised edition should be published every five years. It should be a rule that a third of the questions selected should be of the objective kind and should necessitate the recognition or description of something. By this precaution the evils of cramming might be forestalled, for the crammer must perforce become the teacher of sound knowledge. One great collateral advantage of systematic and exclusively written examinations of the kind suggested would be that those conducted by different bodies might be brought more nearly into uniformity. The written answers should be preserved, and in the case of our own profession ought to be producible at any time on the demand of the General Medical Council. Nor would there be the necessity which is now supposed to exist for the employment of seniors in the profession as examiners. Younger men, having leisure and working under the supervision of an experienced chief, might do the work not only as well, but much better. It must be noted as a distinct drawback in our present system that those employed in it are men whose time and thoughts are very fully engaged in other matters, and who come to their examination work already wearied with that of the day. A never-failing answer to all projects of reform is that the time of the examiners must be considered, and proposals which would involve either extension of time or addition of work are sure to encounter determined opposition. The machinery of examinations will, however, never work satisfactorily until considerations of time and trouble are put wholly aside. Nothing is more essential to just conclusions than that the process should be conducted with leisurely quiet; nor, let me add, should it be in the hands of those who, in consequence of frequent changes and short periods of office, are more or less inexperienced. It is the fashion to hold that anyone who knows his subject can examine in it, but in truth it is not so, and the art of examining is one which, like other arts, needs to be learned. The man who has been some years at work makes, I feel sure, other things being equal, a far more trustworthy examiner than a novice. To some extent, especially in some departments, examining should be a profession in itself. I am aware that there are differences amongst those well entitled to their opinions as to the advantages of subdivision in examinations. It is sometimes sought to throw mild ridicule on divided examinations by speaking of them as "taking your dose in teaspoonfuls." It is thought that by allowing a man to come up in one subject at a time you encourage cramming and voluntary forgetting. I may confess that my own impressions are very strongly in favour of subdivision. In their favour it may, I think, be urged, in the first place, that a much more detailed and practical knowledge may be suitably exacted at a special examination than would be demanded at one which included a great variety of topics. If, for instance, a candidate were allowed to present himself whenever he liked for his examination in ophthalmic medicine and surgery, and to take that subject by itself, he would certainly get it up in a very different fashion from what would probably be the case if he were only going to encounter the risk of a stray question or two as part of an examination in general surgery. He would, in all probability, have attended as an eager and attentive learner at some special institution. Are we to believe that he would forget what he so learnt sooner than he does the scraps of book information with which but too often he is obliged to be content under our present system? He would know well that at such a special examination a much higher standard would be demanded. Having obtained his certificate for eye disease he would proceed with cheerfulness and with a less burdened mind to other subjects. Undoubtedly much will be forgotten. That is inevitable under every plan. It is not, however, so much the mere change of the attention from one topic to another which tends to obliterate knowledge as the fact that the thing had never been really learned at all. We all remember Dr. Johnson's retort to the man who pleaded that he had "forgotten his Greek." In support of the principle of divided examinations it may also be urged that it would permit of the restoration of certain subjects, such as botany and zoology, which have been for well-known reasons left aside, and even of the insertion of others. I am here possibly on delicate ground. Permit me to say, however, that I do most certainly hold that a medical man ought to be a well-educated gentleman, and that he ought not to wholly omit from his training at any rate an elementary knowledge of those branches of natural sciences which are cognate with his special calling. It is quite true that it is no longer necessary to have studied botany in order to prescribe drugs; but there are other and yet more cogent motives for its pursuit. As a branch of the great science of biology it presents us with lessons which are full of interest and instruction. The same is to be asserted of zoology, and with perhaps only little less cogency of geology, climatology, and some other topics. The attainment of knowledge in all these is not difficult if it be sought in the right way. To that end divided examinations—not perhaps compulsory, but resulting in certificates which should be contributory—would be of great assistance.

The advocates of inclusive or comprehensive final examination—and amongst these are, I believe, some of our leading authorities on education—urge with plausibility that they are better tests of a man's memory and mental powers. To some extent this may be admitted, but their superiority in this respect is probably very limited. By no means can it be alleged that those whose memories have sufficed to carry them through an examination in half-a-dozen different subjects on one and the same occasion will subsequently retain the knowledge which they then displayed. The diploma or certificate is, unfortunately, no talisman which will secure us against the treacherous influence of the world's pursuits in obliterating the record of the labours of our student days. Some confession of weakness on the part of the present system is, I think, to be found in the limitations which it has been found needful to impose upon the scope of these many-subject examinations. Students are informed beforehand that only such and such topics will be taken. This is, perhaps, not done so much in our medical examinations as in those of general education. Thus, in botany a candidate at South Kensington is informed that fourteen natural orders only will be questioned in, and that he need not know anything of Papaveraceæ, for example, and a host of others. At Cambridge he must add Papaveraceæ to his repertory, but may still leave aside almost all the rest. At most of our examinations the important sub-kingdom of Fungi may be left out of consideration altogether. I mention these merely as examples; the same principle will be found to pervade other departments, and the result is a sort of patchwork education, the incompleteness of which is much to be regretted. Our children are taught one reign in English history, for instance, or one short period in that of Greece or Rome, and do not obtain, as I think their forefathers did, a general, though it is to be admitted a superficial, view of the whole. Modern education, in its zeal to avoid the charge of being superficial, incurs, as it seems to me, that of being merely fragmentary. It aims at thoroughness, but is obliged

Digitized by Google

at once to admit that it can attain it only in certain subjects, which, compared with the sum of human knowledge, are but few and small. Let those of us who advocate wide study, and as a consequence wide examinations, face at once this charge of encouraging a merely superficial acquaintance with things. There is much to be said in its favour. Excepting a very few of us, we are all mere smatterers as regards almost all that we think we know. It is not possible to be otherwise excepting at the cost of being wholly ignorant in many directions, and as regards fitness for the affairs of life, better by far a general acquaintance with all that is around us, though it be not very deep, than slices of profound knowledge placed sandwich-wise between thick layers of utter ignorance. In the medical profession more especially is this alternating method of education to be shunned. We cannot afford to allow attainments in one direction to counterbalance vacuity in another. Hence I think a very strong reason exists for allowing our students to subdivide their studies and take one at a time, with the understanding that they do that thing, for the time, well.

I must now, Mr. President and gentlemen, attempt a brief summary of what I fear has been a very discursive address, and then conclude. If I have given to any the impression that I am in favour of increased stringency or of increased leniency in medical examinations let me hasten to remove that idea. My plea has been rather that our examinations should become more and more an integral part of our educational system, and that by making them more exact and more definite we should enable them to better assist the labours both of teacher and student. The latter especially should be brought to feel that his examinations, so far from being sources of harass and worry, are really his best friends, in guiding his work and at the same time gauging his attainments. I have advocated frequent examination, but at the same time have urged that the student should be allowed to take one thing at a time, and thus, as it were, to have the pleasure of counting the milestones in his journey. With the hope of reducing to a minimum the uncertainties of examinations I have ventured to suggest some curtailment of the privileges of examiners, more especially that they should no longer be invited to exercise their ingenuity in devising extempore written questions, but should have supplied to them carefully prepared lists of suitable ones, which lists should also be accessible to the candidates. If on some matters I have ventured upon detail which may be thought better suited for a board of examiners than for the present audience my reply is clear. It is time that the public—in the case of our medical examinations I mean, of course, the professional public—should interest itself in this matter. It is one of the widest possible importance, and for reasons which need not now be mentioned it is one in which only reforms of a certain class should be looked for from within. No one conversant with human nature will expect from those actually holding office reforms which might be thought to reduce the dignity of that office. As to *vivâ-voce* examinations, I have suggested that they should give way to written ones. Surely we are behind the day when we keep up the custom of putting specimens into the hands of nervous students and demanding impromptu recognition, when with less expenditure of the examiner's time a quiet hour with half-a-dozen such preparations might be allowed. Who can doubt as to which would best test the pathological knowledge of the candidate? It is the same with the diagnosis of disease in patients.

Many of you listened not long ago, and I believe in this hall, to an address from one whose name stands, I may say without offence to any, as the foremost representative of surgery in Liverpool during the present generation—my friend Mr. Mitchell Banks. He took for his text "the Overcrowding of the Profession." I will not attempt to epitomise an address which was throughout racy with humour and yet solid with sense. With most of what Mr. Banks told you I thoroughly agree. More especially we are entirely at one in his conclusion, which was that the safety of the profession lies, not in new legislation of any kind, but in its own examinations. His chief proposal was to increase the stringency of the matriculation, and thus prevent at once the entrance of the illiterate. In what I have said to-day I have taken up the same idea, but have carried it a little further, suggesting that arrangements should be made throughout the whole course of study which should encourage the industrious and choke off the incompetent and idle. The key to the whole situation is in the hands of the examiner. Curricula of study are worthless without his aid, and certificates of study granted without examination are of no avail whatever. If our examinations were developed we might almost wholly dispense with both, and leave the student almost at his free will to choose and to change his places of study. Only make our examinations trustworthy and thorough and we need no other safeguards. Amongst those who hear me I doubt not there are representatives of different interests in this matter. The student has been much accustomed to regard the examiner as his enemy, and looks upon any suggestion which he thinks would make the test more stringent almost as unmitigated hardship. Paterfamilias, who has sons to pass, takes the same side with perhaps added warmth, on account of a keen recognition of the probable increase of cost. Striving practitioners who have neither sons nor nephews are, on the other hand, willing enough that the portals of the profession should be more strictly guarded. To one and all let me earnestly say that we are all in the same boat. The student of to-day will be the practitioner of to-morrow. It is possible that the supposed evils of overcrowding have been exaggerated, and I am sure that none of us would like to restrict, were it possible, the number of students to that of the supposed needs of the public for medical practitioners. We put a higher estimate on the value of medical training than would allow of our desiring any such protection. From men educated in the schools of medicine have sprung naturalists, men of science, explorers, and those foremost in every branch of knowledge. This has been our boast in the past, let us take care that we do nothing to frustrate it in the future. Let us put no artificial impediments in the way of entrance to our ranks. Let us, however, at the same time, by careful attention to the details of our examinations, make sure of this—that if we are to be overcrowded it shall be by well-educated gentlemen.

OF
INTRODUCTORY ADDRESSES, ETC.,
DELIVERED AT THE
LONDON AND PROVINCIAL MEDICAL SCHOOLS
AT THE
Opening of the Session, 1895-96.

ST. GEORGE'S HOSPITAL.

INTRODUCTORY ADDRESS BY MR. GEORGE D. POLLOCK.

THE following is an abstract of Mr. Pollock's remarks, delivered in the theatre of the hospital:—

"My first duty in appearing to-day in this theatre is to thank my old colleagues and the staff of the hospital and the medical school for the great honour conferred on me in entrusting to me the delivery of what is usually known as the introductory lecture at the commencement of the winter sessions—a duty which affords me much pleasure and satisfaction, for to this hospital and school I owe all my professional success and the association with many sincere and dear friends, some of whom are present on this occasion, but not a few, I regret to say, have passed away from us, leaving behind them the memory of good work done and of lives well spent for the benefit of their fellow men. It may interest you to learn something of the early life of our school and of the arrangements formerly provided for the teaching of anatomy and other subjects."

[Mr. Pollock then gave a short history of the hospital and continued:]

"When I entered here as student in 1837 there were two anatomical schools, with lectures on certain subjects not connected with the building. The lectures on chemistry were delivered at the Royal Institution in Albemarle-street by Brande and Faraday, and many a cold and wet walk have I had to get there at nine in the morning in winter. One anatomical school was in a narrow roadway which ran past the south side of the hospital to Tattersall's Yard, which then occupied a large space of ground in our rear, and upon part of which this theatre, with the museum and dissecting-room, now stand. This alteration was the result of the removal of Tattersall's stables, and for which we have to

Digitized by Google

thank His Grace the Duke of Westminster, one of our vice-presidents and liberal supporters. The other dissecting-room was in Kinnerton-street, at the back of Wilton-place, and there the lectures on anatomy, physiology, and chemistry were conducted. For several years I lectured there on anatomy, often hurried to be in time, after a long attendance in the out-patient room. Not only in this respect are the arrangements for your instruction and comfort materially improved, you have now far greater facilities for clinical work and study. Clinical work being, after all is done and ended, the most important subject to devote your time to, you cannot give too much attention to the aspects of disease or disorders by the bedside with notebook in hand; or, if a fatal termination ensue, to follow the case to the post-mortem room and record there the havoc wrought by disease. Here you will find help and instruction from our curator in the examination of each subject. The study of disease by the bedside, and the investigation of its results when fatal, will lead you to high results only to be attained by persevering labour, amidst many difficulties and oft-repeated discouragements; by labour that chooses its localities as well as its object, and refuses to produce its fruits unless it be amidst the sufferings and sorrows and dangers attendant on sickness and death; by labour that sometimes seems hardly to have begun until we are called upon to follow it in the dead-house, amidst the perishing relics of our fellow-men. But see how morbid anatomy, itself a modern science, enables us to look back, as it were through an avenue, upon the countless paths through which death has made his approach; see how we can track him in his progress, and mark how, step by step, he has gained his territory, and at last has achieved his final victory. But each such victory, if only rightly used, weakens him, while it strengthens us. We learn his wiles, and, increasing our defence, may hope to keep him from life's citadel until at last those threescore years and ten be passed, beyond which life is too often only a prolonged sorrow, whilst death, it is our glorious privilege to know, is the opening of that bright world where disease and pain are no more.

"'Death is the crown of life;
Were death denied, poor man would live in vain;
Were death denied, to live would not be life;
Were death denied, e'en fools would wish to die.'"[1]

[Mr. Pollock then dwelt upon the advantages of holding the appointments of house physicians and house surgeons. He continued:]

"Let me advise you to devote yourselves chiefly during the first winter session to the study of anatomy and physiology. Steadily occupy your time in the dissecting room, and with the assistance of the demonstrations you should almost master your anatomy to such an extent the first winter as to render dissection almost unnecessary subsequently; at any rate, with some work on anatomy, with good illustrations, such as may be found in Quain, you should be able to perfect your knowledge of the human body without difficulty. But work, constant, steady work, is essential to the attainment of this thorough knowledge of the anatomy of man. The study of the structures of the human body, when compared with the varieties of similar tissues in comparative anatomy, is of such interest that it justifies me in commending it to you for your consideration as one of great interest and intellectual pleasure. Compare the muscular development of man with that of some of the lower forms of life; the smallest insect that flies or is seen to creep on the earth possesses muscles as beautifully constructed for movement as are ours for the various actions of our limbs in everyday life. For this a nervous system is provided to call them into motion. What must be the size of that brain or nerve tissues to give action to these muscles? We cannot but acknowledge the beauty, the wonderful structure, and the harmony in all that is the life of that insect, and bow with reverence to the wonderful power that called it into being."

[The lecturer then referred to the celebrated men who had been connected with St. George's Hospital, mentioning specially Baillie, Hunter, Brodie, and Cæsar Hawkins. Continuing, he said:]

"I was much struck by an observation of Mr. Balfour made not long since at a meeting of scientific men which bears strongly in support of what has just been referred to. '*Truth*, not *profit*,' he remarked, 'must necessarily be the motto of every body of scientific men who desire to be remembered by posterity in their discussions.' Gentlemen, your work must be stimulated by honest purposes and rightly directed ambition—ambition for success and a good name, ambition to succeed, if not to excel, in whatever department of your profession your future may be cast.

"'Hundreds before me vain ambition cry,
Thousands behind me common sense reply.'"

Let your ambition be tempered with common sense—rather a rare quality—backed by industry and supported by honest and right-minded conduct; and it is few, indeed, who need fail to gain that success which such conduct in most instances will not fail to secure. But bear in mind still more strongly that it is only too true, 'Ambition is a lottery in which there are many prizes, but in dissipation every man draws a blank.' Now in the practice of your profession there are many circumstances which help towards success. One not to be neglected is your personal conduct in your intercourse with your patients. Some men possess the happy gift of impressing favourably all with whom they come into contact. All do not inherit this valuable quality, but all may endeavour to acquire some portion of it. There can be no doubt that courteous and refined manners have as much influence in practice as great talent; especially is that success secure when the two are combined. Bear yourselves with consideration and kindness towards all with whom you have to deal. Ever remember that in sickness or weakness from disease a patient will appreciate sympathetic attention much more than one in health. A story once told me is perhaps as good an example of the benefits derived from amenity of manner as I can relate. A granduncle of mine who had amassed a large fortune was asked by my father what was the great secret of his success in life. He was a charming old man of most benevolent and lovable disposition. His reply was very simple, but much to the purpose: 'I have always found honey catch more flies than vinegar'—a hint that applies to your intercourse with patients equally to that of its adoption in any other call in life. The *suaviter in modo* is a motto ever to be remembered at the bedside of the sick and should always influence your conduct towards the invalid.

"'To catch Dame Fortune's golden smile assiduous wait upon her,
And gather gear by ev'ry wile that's justified by honour;
Not for to hide it in a hedge, not for a train attendant,
But for the glorious liberty of being independent.'

"Gentlemen, in the practice of your profession you will meet with a great variety of tempers, constitutions, and idiosyncrasies which will require all your care, much judgment, and not infrequently much caution to deal with. Of temper and constitution you will judge best how to manage by careful and judicious observation as cases present themselves to you. But of idiosyncrasies I must say something more.

[Mr. Pollock then referred to the importance of taking note of the idiosyncrasies of patients' foods and drugs, giving several instances, among others that of a gentleman who could not eat gooseberries without their producing an eczematous eruption on some part of the body. When dining with a fashionable party, soon after the champagne had been handed round, the gentlemen observed to a friend sitting next to him—and from whom Mr. Pollock had heard the facts—that the wine was not champagne, but gooseberry wine, and pulling up his shirt sleeve showed him the specific eczematous rash appearing. Mr. Pollock continued:]

"Lord Byron, in his reported conversations with the Countess of Blessington, remarked to her that 'medical men do not sufficiently attend to idiosyncrasies on which so much depends; and often hurry to the grave one patient by a treatment that has succeeded in another. The moment they ascertain a disease to be the same as one they have known they conclude the same remedies that cured the first must remove those of the second, not making allowance for the peculiarities of temperament, habits, and disposition, which last has a great influence in maladies.' These remarks are simple exaggerations of feeling and fact. Byron was not one enamoured of the medical profession more than he was of professors of divinity, but he was an acute observer, and it was interesting to me to read his views respecting idiosyncrasies. He judged rightly, very rightly, of their importance in connexion with the practice of medicine. Observe, gentlemen, that he makes use of the word 'cure' to denote 'treatment'—a word too frequently used without reflection by the world generally, and quite inapplicable to the circumstances of our successful attendance on the sick.

[1] Young, Narcissa, p. 526.

Digitized by Google

The empiric proclaims that the administration of certain drugs, or a combination of them, is essentially a 'cure' of such and such a complaint; but the rightly thinking and experienced medical man will tell you to bear in mind that 'cure' is not a term to be used by the educated practitioner. What can or do we 'cure' in disorders or disease? Nothing, I fear. We treat, and watch with care, 'all the ills that flesh is heir to.' By judicious treatment we may sometimes shorten an attack of illness, and probably do so in many cases of sickness; but the mysteries and course of disease are influenced much more by causes over many of which we have absolutely no control. Take, for instance, the eruptive diseases of childhood or mature life. Do we by treatment cut short the progress of scarlet fever or typhoid fever, or other disorders which need not be enumerated? The late Dr. Wilson, physician to this hospital, a great scholar and a man of great observation and reflection, was ever strongly opposed to the use of the word. It was he who first impressed me with the importance of discarding it as incorrect in all our views with respect to the action of medicines. Patients, he would observe, may recover. 'Recover' under treatment, but we do not 'cure' them. 'Some credit must be given to Nature for her assistance in the recovery.' 'Cure' is the motto of the empiric.

"There is another point of practical importance, gentlemen, to which I particularly wish to direct your attention. You will have to listen to many a tale or history of a case from a patient, or one who in practice may require your coöperation. Listen to all that may be told you with attention and consideration. But, whatever you are told, be sure to satisfy yourselves that you have facts, and not mere statements, to guide your decision, and upon which you have to form your diagnosis and decide your treatment. Take nothing for granted. Take every precaution to establish in your minds the absolute truth of all related to you, and seek for yourselves the symptoms to establish that truth. I heard it once said, and it has remained engrafted in my mind, 'that in medicine, as in most other callings, taking a thing for granted without satisfactory evidence was often the cause of more mistakes than ignorance.'

"Gentlemen, I trust you will not overlook the difficulty there is in giving even the semblance of novelty to thoughts in such a lecture as this—thoughts which have found expression a thousand times by others gone before me on similar occasions to this. My object has been governed by the desire to point out to you certain things which I believe to be true, to be useful, and of universal application; and if anything I have said shall assist in giving a nobler idea of life and its responsibilities to any of you who are now entering on the study of medicine, the purpose I have had in view will be more than amply rewarded. The medical man is often the friend—not infrequently the confidential adviser—of many a patient, quite independently of his professional relations. In this we find how highly the man may be appreciated, not infrequently greatly beloved, and many a time gratefully remembered. When in sickness the patient lies weary and tossing in his bed his mind may be much troubled by some hidden sorrow. The still small voice of conscience may be whispering something in his ear which adds to his unrest and general distress. He may need much mental as well as physical comfort. I do not wish to trespass in any degree on the province of the chaplain; but if, in the distress of mind, added to the sufferings of disease, his confidence in your sympathy and kindness of heart should induce him to refer to his mental trouble you have the opportunity of giving a word of comfort spoken in season.

"Gentlemen, my best wishes attend you, and my sincere hope is that your future will be blessed with health, happiness, and prosperity."

ST. MARY'S HOSPITAL.

INTRODUCTORY ADDRESS BY DR. A. P. LAURIE.

A PAPER was read by Dr. A. P. Laurie on "The Medical Profession and Unhealthy Trades," of which the following is an abstract:—

"In standing before you to-day I must plead complete ignorance of what is customary in opening addresses of this kind, as it has never been my fate to be present on such an occasion, and I have gleaned very little information as to what is expected or what is the nature of the subject usually dealt with. I must confess to having felt somewhat attracted to a discourse on my own department of chemistry and to the expression of views on the reform and development of the teaching of that science in medical schools, where it seems to me less might be asked of the student in knowledge of detail, and more time might be devoted to training by a careful experimental course in the scientific method of thought, thus helping to that scientific habit of mind which would be invaluable to him in his future career. Tempting as this educational question is, and important as the right using of the time devoted to pure science must be, I have decided to leave the subject alone, as I have too recently become a teacher of medical students to indulge fitly in criticisms of our present method of instruction. There is, however, a department of work which falls to many of our students to perform in after life, and which I have had the opportunity of examining into somewhat closely, and on which, therefore, I feel that I have some right to speak. I refer to their duties as certifying surgeons in connexion with the administration of the Factory Acts. It is being more and more widely recognised that we look to our medical men to prevent as much as to cure disease, and though we have not adopted the supposed Chinese method of only paying them while we are well, yet we call upon them as officers of public health, and in various other ways, to protect us from ill-health and to devise means by which disease may be warded off, so that research into preventive medicine and into the questions arising from the difficulties of keeping large and crowded populations in a healthy state are of growing importance. The administration of the various sanitary laws is largely in the hands of the medical profession, and to them is entrusted the guarding of our population from the introduction of foreign plagues like cholera, and from the spreading of diseases that are always with us. Furthermore, all the questions involved in raising and keeping a vigorous and healthy people are in their hands for solution, so that they might well be named the guardians of the public health. And if it is the duty of our navy to protect our shores from foreign foes, to the medical profession is entrusted the far more difficult task of waging an internecine civil war against intestine enemies. Among the many problems of healthy living to which our complex civilisation has given rise few are more interesting or worthy of study than those associated with the growth and development of our industrial system. The necessity for the rapid and continuous production of enormous quantities of articles of commerce has given rise to innumerable difficulties in connexion with the health of those employed in such productions. The insidious effects of long and persistent exposure to influences which for a short period would probably do little harm are pressing themselves on the attention of our medical men and our legislators. For example, the occasional handling of white lead or breathing of a vitiated or dust-laden atmosphere is harmless enough, but prolonged exposure to the same conditions produces terrible results. Attempts, therefore, have been made to meet these evils by special regulations and Acts of Parliament dealing with unhealthy trades, and the Home Office, with its zealous army of inspectors, does what it can to impose these regulations for the preservation of health on the workshop. But though much has been done in this direction much more must be done before results sufficient to satisfy the conscience of the nation shall have been obtained. Few realise who have not investigated them how difficult are the problems involved in this question or how intricate the whole subject is, and yet it is one which has received comparatively little attention from the medical profession. It was my good fortune to be appointed a member of the Home Office Committee which inquired two years ago into the results produced on the health of the operatives by pottery manufacture, and I was specially struck by the fact that most of the local medical men of the district who came before us as witnesses had so little information to give us. Evidently their attention had never been specially turned to the question, and they had missed the opportunity afforded them of making a most interesting series of investigations. There are, of course, many noble exceptions. The name of Dr. Arlidge will always be remembered as a pioneer in this department, and the researches of Dr. Oliver into the poisoning in white lead manufacture have pointed the road to be followed by others; but in spite of these men little has yet been done in the way of scientific inquiry, with the view of remedying the evils produced under modern conditions of industry. In too many of our industries the life of the worker is one long tragedy of physical suffering, and no thoughtful

Digitized by Google

man can study the physical state of the population in many of our manufacturing centres without dreading that in the struggle for commercial supremacy we are sacrificing the health and vigour of our people and are obtaining riches at the price of racial degeneration. Some may reply, Surely our factory legislation has already dealt with these problems, and the necessary steps have already been taken to ward off such dangers. It is true that much has been done, and the laws protecting the labour of women and children and the regulations requiring cleanliness and ventilation have been of incalculable benefit to the industrial population; but the questions which now arise are more difficult and do not the less press for a solution. The whole of the problems involved in the handling of poisonous substances, and in the breathing of a dust-laden and vitiated atmosphere, and in the working in excessively high temperatures, are still in most cases awaiting solution. It is true that the Home Office has made vigorous efforts to deal with some of them by special inquiry and special rules; but, speaking as a member of one of these committees of inquiry, I do not fear to say that the result of that inquiry was to my mind merely to state clearly the problems awaiting solution in that particular industry, but not to solve them, and to prove that it was only by systematic research by trained experts on the spot that permanent and satisfactory results can be hoped for. What, then, is the present state of affairs?"

[Dr. Laurie then proceeded to give a brief historical *résumé* of our factory legislation, adopting as a starting-point the great Consolidating Act of 1878. He continued:]

"This brief historical survey is, I think, sufficient to show that the Home Office has been rapidly acquiring very heavy responsibilities and complex duties with reference to protecting the health of the workers, and that these duties are of a kind which it is surely obvious cannot be satisfactorily fulfilled by the ordinary staff of inspectors. The public are too apt to assume that when special rules have been drawn up the work is completed, while it would be more correct to say it is only then begun. Special rules have not been found adequate to remove those evils in the past and are not likely to prove adequate in the future; they merely form a basis for further inquiry and research. And surely the great advance which has been made as the result of the inquiries of four or five expert committees shows how much might be hoped for from the employment of continuous expert assistance in the future. Let us now look briefly at the reports of some of those committees and see what light they throw on the question. These reports are worthy of study by all medical men interested in public health questions, and contain a great deal of interesting information, but it is impossible to read them and not feel that the information obtained is inevitably imperfect and the proposed remedial measures of a tentative character. In fact, in the report by the Potteries Committee this is brought out very clearly by the committee themselves. They ask 'to be empowered to continue their investigations as to the composition of glazes and colours with a view of finding out how far it is practicable to make a glaze that shall be harmless to those employed and at the same time shall not injure the ware.' In another paragraph they say: 'Further information is also required as to the temperature of potters' workshops and of stoves at the time of drawing the ware.' Further on, speaking of the same subject, they say: 'We have already in Rule 7 attempted to deal with the temperature of workshops, but do not consider the rule in its present shape as final,' and so on. Similarly the reports of the other committees are full of suggestions as to modifications of machinery and processes which would result in far more benefit than the special rules, and which, when adopted by manufacturers, should be carefully watched and reported on from time to time with a view, if successful, to their ultimate universal adoption. Now, zealous and efficient as the factory inspectors are, they cannot be expected, overburdened already by the increasing number of duties they have to perform, to be able to observe what the effects of the special rules are on the health of the operatives, or to discover which are of value or what modifications are necessary, for, apart from the fact that they are already overworked, such observations require a medical training. As an example of a case where scientific observation is required let me take the Cotton Cloth Act requiring the regulation of the temperature and humidity of the air in the weaving sheds. This Act, as I have already stated, has produced a complete revolution in the methods of ventilating the weaving sheds, and gives the opportunity of studying on an enormous scale the results of artificial ventilation on the health of thousands of people, and the value of the new methods as compared with the old. A careful recording of this experiment would be of the utmost importance in guiding us in the ventilation of factories and schoolrooms, and yet, as far as I am aware, no one is watching and recording the results, or, if it is being done, some private enthusiast is engaged in the work, and the Home Office, having instituted this interesting alteration on the air supplied to thousands of operatives, with a magnificent carelessness, does not even watch and record the results of its own experiment. The same criticism applies to the special rules which have been applied to other trades, for they all involve regulations introduced to affect the health conditions under which the operative works, and yet no observations by experts are being made to see if they effect their purpose. We have, therefore, most valuable experiments being made upon this most important subject without any proper record or criticism of the results. But we can go further than this. Questions are arising and will arise in connexion with these special rules and the various modifications of manufacturing processes which are always taking place which the Factory Department of the Home Office, having no experts to apply to, are incapable of solving. I know of one case where a manufacturer applied to the local inspector to be relieved from certain special rules because of certain modifications in processes of manufacture, and the question was referred by the inspector to the Factory Department, referred by the head of the department to the Home Secretary, and by the Home Secretary to the local inspector, and by the local inspector to the manufacturer, who, being the only expert in the whole chain, gave judgment on his own application. What, then, you will ask, is required to enable the department to deal with these questions of increasing difficulty, and to advance further in its battle with disease and death? There are two proposals which I should like to suggest, and which are, I think, worthy of consideration, proposals dealing with the central and the local organisation respectively. In the first place, to deal with the local organisation there is a body of men to whom I referred in the beginning, the certifying surgeons, of which sufficient use is not being made. Let me begin by briefly stating the present position and duties of the certifying surgeon. He is appointed by the Factory Inspector of the district and has two duties to perform. In the first place he has to examine all children and young persons in his district who are about to be employed in factories, and without his certificate of fitness they cannot be employed. For this duty he receives from 2*s.* 6*d.* to 7*s.* 6*d.* for each visit, and 6*d.* for each child examined over five in number, when the examination is made at the factory, and 6*d.* for each child when at some place appointed by him. This is done only in cases when the number of children is under five. In the second place, accidents must be notified to him, when he must go and make an inquiry, and has a right of entry into the factory for this purpose. A special fee is paid for this also. Now, is it not possible to extend the powers and duties of the certifying surgeon, and, if I may make a further suggestion, his pay? Would it not be possible to use him to make continuous observations on the health of the operatives and the effects of new regulations and report to the Home Office on the same, and would not the money so expended be well spent, and is it not worthy of consideration whether the status and method of payment of the certifying surgeon could not be improved? I know of one certifying surgeon who has received exactly 2*s.* 6*d.* in fees in three years, in return for which he had to fill up innumerable forms and reports to the Home Office. This can hardly be regarded as a lucrative appointment. In fact, we have here an expert staff already in touch with our factory system, and responsible for the fitness of the operatives at the beginning of their career, which might, if properly encouraged, supply us with invaluable information; and, furthermore, in the Factory Act of 1895 a clause has been introduced giving power to the Home Secretary to call on the certifying surgeon to make special inquiries, which opens the door to my proposal. But it is not only locally that the expert is required; the work done by the temporary expert committees appointed by Mr. Asquith has shown the value of expert advice. Why should not the Home Office have an expert consultation committee attached to the factory department, consisting of medical men, manufacturers, men of science, and engineers, who should have power to inquire into and report on and advise on questions affecting the health of the operatives?

Digitized by Google

In this way much useful work could be done. So far I have only treated of this matter from the point of view of the operative, but I am sure the manufacturer would also welcome my proposal. He, too often, feels that he is subjected to vexatious regulations, involving trouble and expense, but which do not go to the root of the matter, by a department which, though well-meaning, is ignorant; and, while willing to submit to such regulations when evidently leading to improvement in the health of his work-people, he is irritated by restrictions which he knows to be useless. Such an expert committee would give him more confidence in the factory department and make him submit to their conditions with better grace. It is, therefore, in this direction that I venture to think the next step in advance is to be made, and, in conclusion, I would wish to press upon our future medical men the importance of these questions. Noble as the work of curing disease undoubtedly is, that of preventing disease is nobler, and there are many thousands in our great manufacturing cities the victims of our industrial conditions, living lives of hopeless ill-health, that are looking for deliverance—a deliverance which is only to be obtained for them by men who combine the calm, clear intellect of the man of science, with a burning compassion for the sufferings of their fellows, a combination of qualities which is to be found most frequently in the medical profession."

MIDDLESEX HOSPITAL.

INTRODUCTORY ADDRESS BY DR. JULIUS MICKLE.

THE address was chiefly devoted to discussing the manner in which the knowledge of a simple external object is obtained, and in drawing therefrom conclusions as to the only proper, natural, and fitting methods of medical study.

In the first place, it was shown that in the mental development of children the acquirement of a knowledge of a simple object is a gradual affair, and only succeeding after many attempts. That, simple as it may appear, is only arrived at gradually and after failure of the earliest attempts, so that only little by little is the knowing achieved; and any very early error must be corrected by subsequent experience; so that there is a process of learning, and of overcoming difficulties, in order to know the simplest object. Applying this to medical study, it was pointed out that if the natural and fitting method be followed the process must be gradual, that it must begin with the most simple, which must be thoroughly mastered before the study of the more complex is undertaken. In the second place, in knowing a simple object, of a certain class, there must be a synthesis of the evidence derived from certain senses concerned, and a conjunction of that of the several senses coöperating in the process. The importance of the sensations of sight, of touch, and of those attending movement was indicated, and the inextricable manner in which the feelings of movement are bound up with the visual and tactile sensations was insisted upon. The importance of the movements of the eye and hand in vision and in active touch was referred to, and the sensations derived from other senses—such as hearing, taste, and smell—were shown to have their part in the process of perception of the particular object which was used in illustration of this part of the address. In the application of this to medical studies, it was maintained that in them it is necessary as far as possible to use all the activities of the mind and to use them in coöperation. The importance of great width of culture in medicine was asserted, and the characters were mentioned which any sound specialism must possess, and especially that it must be built on the firm foundation of a wide and complete study of medical and other science. In relation to this, and as examples to follow, were mentioned the wide bases on which were built the medical acquirements of two eminent members of the profession recently lost by death—one Mr. Hulke, who, having a profound knowledge of general surgery, was also an expert in ophthalmic science, was of great repute in palæontology, and of very considerable attainments as a linguist. The other was the late Dr. Bristowe, who, to a profound knowledge of general medicine, had added a special knowledge of pathology, and of diseases of the nervous system, abdomen, and skin. In the third place, for accurate knowledge of the simple object it was shown that there is a process of search for accuracy, a process (so to speak) of working towards truthfulness, so as to secure a truthful mental representation of the object, and to correct any error of sense by the truthful evidence of other senses. And, moreover, that what is true with regard to these simple products of mental activity is true also of the outcomes of all the higher and the highest activities of mind and their collateral results, and therefore involves the accuracy of the highest thoughts or ideas. This proved the necessity of using in medical research and study the utmost fidelity, the honest intention of truthfulness to nature, and the necessity of correcting any error that may arise by the critical operation of other forms of mental action. And, in regard to this part of the subject, the predominant importance of making medical study as faithful as possible to nature was urged, as well as that in medical research and study there should be a perfectly unbiased, fair, consistent, judicial frame of mind, employing in its service all the modes of mental action, and honestly seeking to attain that which is true; that, in a word, medical study should be an honest, consistent, persistent search for truth, and made with all the powers of the student and practitioner.

Other topics relating to the main one were also touched upon.

ST. BARTHOLOMEW'S HOSPITAL.

INTRODUCTORY REMARKS TO THE COURSE OF MEDICINE BY SIR DYCE DUCKWORTH.

"IN beginning to-day the course of systematic lectures on the Practice of Physic, I have little to add to the introductory remarks I ventured to offer to those who sat where you now do at this time last year. I then counselled the importance of systematic prelections in opposition to a modern, and still prevailing, opinion that the day for such a method of teaching had passed by, and that the best training in medicine was only to be gained by an expansion of the tutorial system and by assiduity at the bedside of patients. I entirely accept both of the latter methods, and we afford you in this school the largest measure of each of them. But I no less strongly insist on the great value to you of a diligent attendance on systematic lectures in medicine, surgery, and midwifery, in addition to your tutorial and bedside work. You need all of these. Our systematic courses are now shortened and disencumbered of much that was imported into them in my student days, and I venture to believe that you may gather much from the experience of your senior teachers, which, be it remembered, reposes on a larger basis of observation than can be had from even the fullest hospital opportunities. I may here and now tell you of the activity that is on all hands prevalent in research bearing on practical medicine. Almost every problem is the subject of careful inquiry, and these pursuits are followed with a remarkable degree of industry by an army of trained investigators. We note the patient scientific research student, working often with no other prospect than that of the hope of discovering the secrets of Nature, not seeking mere results, but for the precious kernel of truth. And in labours such as these how little do we think of the failures and disappointments that always befall honest investigators—almost heartbreaking when the expenditure of time and effort is considered. We seldom, indeed, hear of these, but now and then we have the curtain lifted and the light let in with startling effulgence. A line of thought such as this leads me at this moment to recall to you the glorious life-work of that splendid French *savant* so lately taken to his rest amidst the regrets and affection of his compatriots and of scientific men the world over. The life of Louis Pasteur was in every sense a full one. Though not a member of our profession, he probably did more for practical medicine and surgery than all the physicians of this century. This is not the time, nor am I the person, to descant at length on the triumphs of his patience, perseverance, and genius. You are familiar already with many of them. Unselfish, modest, unspoiled by success, fearless, simple, a fervid patriot, a true Christian—such was this great and good man. What a career is his to contemplate in these days of indecent pushing and self-advertisement, what a magnificent lesson does his life afford to those who labour for the truth's sake, and what a moral loftiness it sets before all of us. Think of the aspersions and calumny often cast upon him, and how he bore with the taunts and puling nonsense that were hurled at him by silly sciolists. Like the waves beating on the rocks, like the idle wind, to him all these. He went on his way with the one great aim to seek God's truth, to help his suffering fellow-creatures,

Digitized by Google

and to show to his generation and to all who shall follow him how the secrets of Nature are alone to be wrested from her and placed amongst the eternal certainties. We cannot yet tell all we owe to the labours of Pasteur, but we feel sure that no man ever did more to help us as physicians and surgeons, and we cannot doubt that many generations in the days to come will rise up and bless his name. 'Exstinctus amabitur idem.'"

THE PHARMACEUTICAL SOCIETY.

INTRODUCTORY ADDRESS BY PROFESSOR FREDERICK T. ROBERTS, M.D., F.R.C.P.

THE address was delivered before the society by the lecturer on Wednesday, Oct. 2nd, 1895.

After some introductory remarks Professor Roberts drew attention briefly to the history of the Pharmaceutical Society and School of Pharmacy, and eulogised the founders of the institution, as well as its professors and teachers from its establishment until the present time. Addressing the students, the lecturer then proceeded to lay before them certain thoughts which had suggested themselves to him, and which, he trusted, might not be without some influence for good. He continued:—

"First, entertain and cherish constantly a high conception and standard in relation to the nature of your calling, its purposes and aims, its possible achievements, and its social status. It is of no use attempting to conceal or deny the facts that in past times the business of a 'chemist and druggist' was generally but a 'paltry trade,' and that the apprentice who was supposed to be learning pharmacy was often nothing but a 'shop-boy employed to fetch and carry.' Indeed, I very much fear that such a description will still apply not uncommonly. This ought not to be, and pharmaceutical chemists as a body should do their utmost to make it impossible for such a state of things any longer to exist. But obviously if pharmacy is to reach and retain its proper and legitimate status, those who are engaged in its practice must be adequately instructed and trained. I cannot now enter into any discussion as to what should be the exact scope and extent of the instruction and training, or the range and degree of severity of the examinations, especially as I understand that on these points there are differences of opinion even amongst those who have the interests of pharmacy at heart. I venture to affirm, however, that the higher you aim, within due and well-understood limits, whether in regard to general culture, instruction in your own special subjects, scientific and practical training, or qualifying examinations, the better will it be for pharmacists as a body as well as for the community at large. Of course, the fact must be fully recognised that the pharmaceutical chemist cannot ignore the business aspect of his vocation, but I really cannot conceive of anyone, because he is an 'educated pharmacist,' being ashamed of his business. And here let me say that, speaking personally, I certainly do not claim any abstract social superiority for the vocation of the medical practitioner over that of the pharmacist, or that there is any line of demarcation between them. Their relative position must very much depend on individual attainments, character, and actions; and in my opinion the educated pharmacist may fairly regard himself as a 'professional man' if he acts accordingly, and 'carries out everything in a true professional spirit.'

"I now proceed to deal with another point which experience has taught me that it is desirable and necessary to urge and impress again and again upon students, especially upon those who are beginning their career. It is that you should conscientiously realise your responsibilities and fully appreciate your opportunities, taking the utmost advantage of the excellent means of instruction and training, both scientific and practical, which are now at your command. Certainly your advantages here are great, and I strongly advise you to live up to them. To pass your necessary examinations is the lowest point that you can possibly aim at, but you may go as far beyond as your ambition prompts or your opportunities permit."

[Professor Roberts then proceeded to refer to certain practical questions bearing upon the relations existing between the medical profession and that of pharmacy. He affirmed that there is certainly no inherent antagonism between the medical man and the pharmaceutical chemist in any sense whatever, as a superficial glance at much that is going on might lead one to suppose. On the contrary, there should be nothing approaching want of harmony or discord between them, and they ought to work together earnestly and cordially for the common good. He then continued:]

"Assuming, then, that we are well-disposed towards each other, I, as a member of the medical profession, claim from you pharmacists protection against certain dangers and evils with which we are really impotent to deal. In the first place we look to you to guarantee, within reasonable limits, that we are supplied with efficient, active, pure, and unadulterated drugs. Moreover, I cannot refrain from saying a few words about what I may term 'irresponsible pharmacy,' upon which I very much wish that the Pharmaceutical Society could exercise some check. Pharmacy is really in a somewhat curious state just now, and the number and variety of preparations and compounds one sees advertised for every kind of complaint, each vying with the other in brag and boastfulness, are positively most confusing and overwhelming. Up to a certain point of course this is very pleasant and helpful, but there are limits. Amongst other matters, I affirm that it is decidedly wrong that so many drugs, some of them very powerful and even dangerous, are now supplied freely to the public at large in the form of tabloids, capsules, and the like, which they can consume or use in other ways to any extent at their own discretion, and altogether apart from medical supervision. Again, I must enter my emphatic protest against the extreme haste which is exhibited to flood the market with all kinds of new drugs and special remedies, in endless variety of preparations and methods of administration, either before they have been fairly studied or tested at all, or only in a most superficial and inadequate manner."

[Professor Roberts then said that in order to maintain cordial and friendly relations between medical men and pharmacists he presumed it would be generally agreed that it is most desirable that they should keep to their respective spheres as strictly as possible. He discussed the question of dispensing by general practitioners and regretted that for obvious reasons this long-established custom could not in the meantime be changed. He then proceeded:]

"There is another aspect of affairs which I feel bound to notice, though I may be venturing on delicate ground. I allude to the 'prescribing chemist.' Whether I give offence or not, I must unhesitatingly and emphatically declare that for him there is no excuse whatever. He has never been educated or trained in any sense for the position which he assumes, and is certain to do infinite harm in a variety of ways. Therefore I earnestly exhort you, whom I am now addressing as students, from the very outset steadfastly to resist every temptation to resort to such a practice, and not to be led under any circumstances into what is an unfair and illegal competition with the medical profession. I feel ashamed to acknowledge that there are practices prevalent amongst a certain class of qualified medical men which are not one whit better than those of the 'prescribing chemist.' The running of 'cheap dispensaries,' where 'advice and medicine' are supplied to all comers without the slightest pretension to 'clinical investigation,' and, as a rule, at a figure that I feel sure would make you blush if I mentioned it; and the extensive employment by medical men of 'unqualified assistants,' who are absolutely ignorant and incapable, and not a few of whom are but the wreck of immoral and degraded lives, are standing blots upon our profession, and it is a scandal that it is possible for such practices to continue.

"It is pleasant to pass from controversial questions, and to consider for a moment that of coöperation, which in these days is such an attractive word. Taking a comprehensive glance at the existing state of things, and looking forward into the future, one cannot fail to see many directions along which the authorities who guide the affairs of the medical profession and the Pharmaceutical Society, as well as the general body of members of the respective branches, may and ought to work together on legitimate and rational lines. I believe that we all desire a higher standard of education, and that true knowledge and culture may be more widely disseminated among our ranks. What will be the actual course of events in the future it is difficult or even impossible to foretell. The administration of internal organs or their products in different forms; the introduction of serum-therapeutics, with the injection of antitoxins and the like; the development of physical methods of treatment; and other modern therapeutic novelties, are unquestionably revolutionising our ideas about treatment in many respects.

Digitized by Google

For some notions and expectations still widely entertained there is no foundation whatever, and amongst them I confidently affirm is that of the cure of pulmonary phthisis by subcutaneous injections of various kinds. I thought that this craze had received a salutary check, but I see it has recently broken out again violently in a new place. Apart from other aspects of the matter, it is a cruel thing to hold out such illusory hopes to those suffering from this terrible disease, for which so much can really be done by rational methods."

[Professor Roberts then addressed a few words of general exhortation and encouragement to the students, and concluded as follows:]

"And now, in closing, let me offer my cordial congratulations to the successful winners of prizes and distinctions who have come before us to-day, and my no less cordial encouragement to those who for the present have not achieved all that they aimed at or desired. May you all work on loyally, steadfastly, hopefully, and cheerfully, conscientiously striving to fit yourselves for the important public duties that lie before you in the future, so that, whatever position you may in the course of events be called upon to occupy, you may be enabled, not only as accomplished and successful pharmacists, but as men and women of 'high personal character, moral rectitude, and fine sense of honour,' faithfully to serve your day and generation, and to contribute your due share to the well-being and progress of humanity."

LONDON SCHOOL OF MEDICINE FOR WOMEN.

INTRODUCTORY ADDRESS BY MISS ELLABY, M.D. PARIS.

MISS ELLABY began by reminding the students of the legend of the House of Busyraine, comparing the treasure of knowledge to Love's Prisoner well guarded within the house by three iron doors, for which each one must find the key for himself. She continued:

"Over each door was an inscription; over the first, 'Be Bolde'; over the second, 'Be Bolde, be Bolde, and everywhere be Bolde'; but over the third came a sudden check—'Be not too Bolde.' In the search after medical knowledge students would do well to adopt these mottoes as emblems of the courage, tempered by wisdom, required to seize and to put to its best use this treasure when found. But 'life is short, art is long,' &c., says Hippocrates, so in addition we need haste, but with the same check—not too great haste. *Festina lente*—make haste slowly. This triple armour—Courage, Wisdom, Speed—will prove all-sufficient for any battle. The study of medicine should be, like all other kinds of education, 'brave and preventive.' For this we need the all-round development of our whole nature, which will give us the power to grasp all details of a question, and to approach it from a higher level; in this way our judgment will be divested of every personal element, and we shall be enabled to act without vacillation or delay. Very close to this comes the question of our relation with other people or our manners. These should be the 'happy way of doing things,' and this 'happy way,' if we have it, helps us on to cultivate and to possess a real sympathy with others—one of the keys by which to unlock the secrets in nature. This sympathy will also make us tolerant and large-minded enough to appreciate other people's opinions and judgments even when they differ from our own. On the importance of health, especially in connexion with the bugbear of over-work, I fear 'others' follies teach us not,' and we must each fight our own battles: provided only that the experience gained does not come too late, and that our precious Pegasus of health is inside the stable and not outside when at last we proceed to shut the door. I will refer to one point only, and that is the temptation, which I think besets every earnest student at the outset, to spend too many hours consecutively at work. The attempt to accumulate many facts is only satisfying for the moment, for facts must soak into the mental soil, and not lie upon it. The object of our study is the cultivation of our reason as well as of our understanding; we should not, therefore, overload our minds with facts, but regard them as a means to an end, and not the end itself. Above all, do not grudge the time spent in recreation and outside your work, for it is then that our fuller and larger views of life come to us. I do not think the advice the Emperor Alexander gave to the Poles, 'Above all, no dreams,' good for general application, for in the somewhat prosaic details of our daily life they come as a help, and not as a hindrance, if we keep them in a right proportion to work or action. So I would say again, Do not overcrowd the day with work, but give yourselves time for recreation, thought, and meditation, and even for dreaming—have, in fact, the leisure that the busiest people often possess, which is much more the habit of an open mind than the actual amount of spare time to be disposed of. In your career there will be valuable opportunities, which will be very much what you choose to make them. It has been said that the tragedy of all souls lies in the gulf which separates our ambition from its realisation, and we, who look back, find that the saddest elements there are our wasted opportunities. Do not let them slip, but seize them at the right moment; for 'Occasion,' says Bacon, 'turns a Bald Noddle after she hath presented her locks in front, and no hold taken ..... there is surely no greater wisdom than well to time the Beginnings and Onsets of things.' It is perhaps too fatalistic to say that 'character is destiny,' but it is nevertheless true that our destiny is very much what our character makes it. We must lean on ourselves, turn our talents to account in every particular, and be, as Goethe says, 'not the creatures but the architects of circumstances.' You are all to be members of a very noble profession, and you have each one a fine career open before you. It is not in the power of everyone to be a genius or to make a mark in the world, but it does rest with each one of us to make, as Jean Paul Richter says, 'as much of ourselves as could be made out of the stuff.' This is only to be done by steady all-round work and patient, humble searching after truth. In this way we can all endeavour to contribute our mite, not only to the use but also to the beauty of life, for 'all things are for the sake of the good, and it is the cause of everything beautiful.' I will, conclude with the words of one of our greatest philosophers specially applicable perhaps to the student in medicine: 'And, generally, it is good to commit the Beginnings of all great actions to Argos, with his hundred eyes; and the Ends to Briareus, with his hundred hands: First to watch, and then to Speed. For the helmet of Pluto, which maketh the Politicke Man goe invisible, is, Secresy in the Counsell, and Celerity in the Execution.'"

YORKSHIRE COLLEGE, LEEDS.

INTRODUCTORY ADDRESS BY DR. D. J. LEECH.

THE lecturer, who is Professor of Materia Medica and Therapeutics at the Owens College, Manchester, chose for his subject "Our Forefathers." The address was delivered at the opening of the Medical Department of Yorkshire College, Leeds, on Oct. 1st. After some introductory remarks he continued as follows:—

"Mr. Herbert Spencer in an article in the June number of the *Contemporary Review* claims for the medical profession a sacerdotal origin. He points out that the union of the functions of physician and priest is a normal trait in early societies, the priest being the recognised physician in some, whilst in others the physician has assumed to a considerable extent the functions of the priest. Even the medicinal effects wrought by plants were, he thinks, originally attributed to the spirits dwelling in them, and the medicine men of uncivilised peoples have always combated disease by driving out evil spirits as well as by natural remedies. He considers, however, that the physician originates rather from the priest properly so called, who deals with ghosts, not antagonistically, but sympathetically, than from the native medicine man. The priestly caste, he says, in an early state of civilisation develops culture, and from part of this culture having its origin in previous stages comes greater knowledge of medicinal agents, which gradually cease to be considered as acting supernaturally. Mr. Spencer, then, seems to be of opinion that treatment by remedial agents owes its introduction to ideas concerning the supernatural, that the priesthood added to medical knowledge thus initiated, and that medicine and the medical profession of the present time have originated from the basis thus established by them. This view, I think, is open to many objections. Doubtless, a very close connexion has existed from very early times between medical treatment and the belief in the efficacy of supernatural means for the cure of disease; but it seems to me there is no evidence that the initiation of the treatment of disease by remedial agents has developed from ideas relating to the part which gods and supernatural agencies play in the production and cure of disease.

"The origin of the treatment of disease by remedial agents was the subject of speculation in very early times. It has been thought by some to have sprung from the same

Digitized by Google

instincts which seem to lead animals under certain conditions to eat when ill substances they usually avoid; others—e.g., Schmiedeberg—have suggested that man has imitated the habits of animals in this matter. In the treatise of ancient medicine included in the works bearing the name of Hippocrates, and which Littré believes were written by the Father of Medicine himself, the belief is expressed that medical treatment arose from observations on the different influences of foods and their properties in health and disease. In connexion with this view it is interesting to note that in the earliest works relating to treatment dietetic substances play a leading part in remedial agents. The oldest document bearing on medical matters we possess was discovered in 1889 at Kahun, near the pyramid of Illahun, in the ruins of an ancient town which has been apparently inhabited by the builders of the pyramid. It dates from the Twelfth Dynasty—2700—2500 B.C., more than 1000 years before the Exodus. It consists of instructions for midwives and includes prescriptions for treatment. Into these, articles of diet largely enter—namely, beer, cow's milk, oil, dates, and other fruits, herbs, sweet beer, honey, onions, &c. In the prescriptions of the medical papyrus obtained by Ebers at Thebes, and usually bearing his name, the same feature is well marked. This most ancient of pharmacopœias was found between the legs of a mummy. There is a general consensus of opinion that it was compiled about 1500 B.C., though some of its contents date from an earlier period. It consists of formulæ for the treatment of a large number of ailments, both external and internal, some very simple, consisting of one or two ingredients only; others more complex, containing twelve to fifteen drugs, and directions more or less precise are given for their preparation and use. Most of the drugs are derived from indigenous plants, but a few minerals, such as alum, salt, nitre, and sulphate of copper, are also found in them. Some of the ingredients cannot be recognised.

"In the prescriptions of the papyrus of Ebers dietetic substances largely predominate; honey, milk, bread paste, several cereals, fruits, such as figs, plums, grapes, melons, and dates, and like substances are found in a very large proportion of the prescriptions, and that they were not used simply for flavouring purposes seems evident from the fact that many of the medicines are entirely composed of them. It is probable, too, that in addition to the large number of substances in this pharmacopœia which we recognise as foods many of the other components which we look upon as drugs were used in ancient times for culinary purposes. Maspero points out that in the time of the Pharaohs castor oil was probably taken regularly in food; indeed, it is yet a favourite condiment amongst the Egyptian fellaheen, who flavour their salads with it. He thinks that the Egyptians 'began by eating every kind of food which the country produced. Many of these, when their therapeutic virtues had been learned by experience, were gradually banished as articles of food and their use was restricted to medicine; others fell into disuse and only appeared at sacrifices and funeral feasts.'

"In the drugs used by savage tribes foods and substances capable of being used as such predominate as they did in Egypt of old, and, as was the case in Egypt, active poisons are comparatively rarely used as medicines. As medical knowledge has advanced, foods have been for the most part replaced in the treatment of disease by more active agents, but they have not yet entirely disappeared. The lettuce and pearl barley, with its preparation decoctum hordei, are to be found in the list of remedial agents in the present edition of the British Pharmacopœia, and constitute a connecting link between the medicine of the present day and its origin in the dim past. It is not difficult to account for the prevalence of foods and the absence of active poisons in primitive medicine. The favourable changes in certain forms of disease which follow vomiting or excessive action of the bowels, skin, and kidneys must have attracted the attention of man in the earliest stage of his development. In his search for food he would note in the first place the substances which, when taken, cause death soon, and these he would entirely discard. His attention would also be drawn to certain animal, vegetable, and mineral products giving rise to vomiting, purgation, diaphoresis, or diuresis, and even the most untutored mind would infer that advantages might follow their administration in the diseases where emesis or an increase of the secretions had been found beneficial. The character of the earlier formularies and of those of uncivilised people points to an origin of medicinal treatment from observation, and it is from this treatment that has sprung the medicine of to-day. That arising from superstitious ideas has been gradually discarded.

"By what class of people was the treatment of disease introduced? Who were the earliest forefathers of the medical profession? Mr. Spencer says the priests, giving as a reason for his view the close connexion of the function of the priest and physician in early societies. As we go back into Egyptian medical history we do not find evidence of a greater influence of the priesthood in medicine, but rather the reverse. In Greek literature the earliest allusion to the healing art is found in Homer, who represents it as derived from the gods indeed, but in the hands, not of priests, but of warriors, and, to a certain extent, of women. The only two physicians named in the Greek army are Machaon and Podalirius, who were also warriors and led thirty ships to the siege of Troy. Their father, Esculapius, is represented as a chieftain to whom Chiron taught the healing art as he did to Achilles. There is no allusion to temples open for the sick or to priestly medicine. How early a distinct medical class was developed out of the primitive system of medical practice which the Homeric poems delineate is not known. Pythagoras (580–510 B.C.) and other philosophers mixed up a little practical medicine with their speculative doctrines. At the end of the sixth century we hear of a famous Greek physician, Democedes, curing the King of Persia when the Egyptian physicians failed, and at the end of the fifth a Greek, Ktesias, was physician to the Persian Court, and Hippocrates wrote his famous works. In almost all, if not in all, countries there are practitioners of medicine. Jagor, however, could find none amongst some of the tribes on the Philippine Islands, and von Rosenberg denies their existence in a tribe on the south-west coast of New Guinea; but it is quite possible that in both cases they were overlooked. Statements with regard to the absence of medicine men and the use of drugs in wild tribes must be accepted with reserve unless the reporter has lived with them. In the Andaman Islands there seems hardly any indication of a medical class, and often medical treatment is undertaken by the wife of the household. Amongst the old Peruvians, too, the old women acted, at least in the case of the common people, as their medical attendants, and in South Australia—in smaller ailments, at least—each one is his own physician; but these are exceptions. Almost everywhere we find medicine men. Sometimes, as in New Guinea, they are hardly differentiated from the other people. In most tribes, however, they form a distinct class, and often they hold a high position. Amongst the Dakota Indians they have the highest respect paid them, and they are the most influential people in the aboriginal tribes in Victoria and amongst the Ipurian Indians. In Samoa, however, they seem to occupy the highest position of all; in one place, at least, Turner found that an old medicine man was looked upon as the incarnation of a god. But this is no evidence that they are necessarily connected with the priesthood, although they deal largely with the supernatural.

"From what we can learn of the past, and what we can observe among uncivilised people of the present day, it seems probable that a knowledge of the influence of drugs on external or internal ailments has tended everywhere to accumulate in the hands of certain individuals—usually, perhaps, in those of the chief of the tribe, sometimes in those of his wife, but not infrequently other members became the special depositories of medical knowledge. Schmiedeberg suggests that such knowledge would first accumulate amongst herdsmen. Eventually differentiation of function occurred. Doubtless this was a gradual process and was accomplished in many ways. At times it may be that the priesthood took part in it, but there is no evidence that this was always or even often the case."

[Dr. Leech then dwelt on the connexion between medicine and the supernatural and traced the progress made by the healing art from the time of Hippocrates. He continued:]

"I think I have shown that the practice of medicine has arisen from observation and not superstition, but whether I have or not you who are entering the profession may rest assured that careful observation is the corner-stone of medical work. Above all things cultivate exactness in your observations. It is through want of exactness that more advance has not been made in medicine. Not a tithe of the drugs which have burdened the pharmacopœias of all ages,

Digitized by Google

including the present, would have been found in them if observation had been exact as to the value of remedies. Always keep in mind the well-known aphorism of Hippocrates: 'Experience is deceptive.' Mistrust your own observations at first and do not on too slight grounds assume they are correct. Confirm them by repetition. In much of your work in your student career you will find good opportunities for exercising yourself in exactness, and in none more so than when you are taking notes in the hospital wards. It is then that you have for the first time the opportunity of making observations in practical medicine for yourselves. Make good use of it. It is carelessness in observation in the wards which often leads to unsatisfactory results at a later period. I have told you to mistrust your own observations—equally mistrust those of others. Above all things beware of accepting hypotheses as facts. Many so-called laws are really only what are called working hypotheses—that is, theories which are put forth as possible truths, to be used in a tentative manner as guides to further experiments. Reasoning based on them has no firm foundation, yet they are often used.

"Although observation is such an important matter in medicine, yet for its progress much more is wanted. It is probable that the healing art had been cultivated, and with some care too, in Egypt for at least 3000 years before the Papyrus Ebers was compiled. But although this book contains much that is true and useful it indicates that but a slight advance in real knowledge had been made. This arose partly from the imperfect observations, but partly from the fact that the art of healing cannot advance far by simple observation of what does good in individual ailments—a knowledge of many collateral subjects is essential. You will not gain by devoting your attention as exclusively as you can do to what may be called the practical details of medicine, surgery, and midwifery. Physiology, chemistry, and pathology are not subjects merely to be slipped through with the idea that they are of no active service. The harder you work at them, and the more full your knowledge of them, the easier will you find what are often called the more advanced subjects, and the better medical men will you make. Neither as students in after life try to limit your acquisition of knowledge simply to the methods of cure, for if you do you will limit your knowledge of the methods of cure. Physics, chemistry, anatomy, and physiology will all stand you in good stead in the practical work of your profession. For the advancement of medicine they are absolutely essential. Do not treat these subjects as if they were to be acquired for examination simply, and to be forgotten as soon as possible. In your medical work, gentlemen, remember the injunctions of Hippocrates to watch the course of nature and bear in mind the necessity of always trying to find out the natural course of disease, that you may be the better able to treat it. How much misery would have been prevented if medical men of old had known that many conditions which they thought required the most energetic treatment would get well if left alone.

"Finally, gentlemen, remember the teaching of Hippocrates with regard to conduct: 400 years B.C. it was considered essential that a medical man should pass his life in purity and holiness; that he should respect the confidence of his patients, and that he should be careful of their feelings; that he should be ever on his guard lest what he prescribed should do harm; and that he should avoid all kinds of charlatanism. These and many other injunctions should press on you, living in the nineteenth century, even more strongly than on those who lived before our present era. Let me strongly urge you never to forget the teaching in this respect of the great Father of Medicine."

MASON COLLEGE, BIRMINGHAM.

INTRODUCTORY ADDRESS BY PROFESSOR PERCY FRANKLAND.

AN address was delivered at the opening of the Medical Session at Mason College, Birmingham, on Oct. 1st, by Professor Percy Frankland, F.R.S., on Pasteur and his Work: the Debt of Medicine to Chemistry—of which the following is an abstract:—

It may be said without exaggeration that there is no scientific name which is so universally known and in so many different connexions as is that of Pasteur. The chemist, physicist, biologist, and medical man each view Louis Pasteur as the author of some of the most important, novel, and fruitful departures in their several branches of knowledge, whilst in the worlds of industry and agriculture his influence has also been deeply felt and gratefully acknowledged. The first subject of research taken up by Pasteur at the early age of twenty-five was of such an abstract character that if his career had terminated with its completion the general world would have never known his name, and yet the initiated few would have been able to recognise one of the shrewdest scientific observers of this or any age. His strict mathematical and chemical training led Pasteur to be fascinated with the wonderful geometrical forms which are assumed by solids in what is generally called the crystalline state, and the particular phenomenon which attracted his attention was the existence of two tartaric acids apparently identical in chemical composition, in chemical properties, and in crystalline form, and, in fact, in all respects excepting alone that the solution of one had no effect on polarised light, whilst the solution of the other turned the plane of polarisation to the right. Submitting these crystals to the most searching scrutiny, Pasteur found that there were some minute faces on the crystals of the active tartrate which were absent from the crystals of the inactive tartrate, and such importance did he attribute to these little faces that he recognised that their presence relegated the substance possessing them to an entirely different class from that to which belonged the substance not possessing them. The crystals of the inactive tartaric acid which were destitute of these little surfaces he found were symmetrical, whilst the crystals of the optically active tartaric acid he found were unsymmetrical, or "dissymmetric," as he called it. His speculations, subsequently developed by Wislicenus, Le Bel, and Van't Hoff, led to the foundation of that most fascinating and fertile field of chemical science now known as stereo-chemistry, and prepared the way for some of the greatest achievements of modern chemistry, such as the artificial production of the natural sugars. Pasteur's genius was, however, not long to be retained in the exclusive service of abstract science. In the course of his experiments on the different kinds of tartaric acid he was led to try the effect of submitting them to fermentation processes, and he found that the two oppositely active tartaric acids are physiologically utterly distinct, one of them being capable of undergoing fermentation by means of bacteria, whilst the other remained untouched. This striking phenomenon has been largely utilised by later investigators for the preparation of new optically active chemical compounds. Pasteur was thus drawn by accident, as it were, from the inanimate world of pure chemistry into the vortex of the world of life, and it was to the study of vital phenomena that practically the whole of his genius and energies was subsequently devoted. The frontier line which Pasteur crossed from the domain of chemistry into that of biology was at the time very ill defined. The phenomena of fermentation which he had attacked were not generally regarded as vital phenomena at all, and it required years of patient labour before Pasteur was able to convince the scientific world of the truth of his statement that fermentation processes were the work of living microscopic organisms, and that each fermentation process was the work of distinct organisms. Knowledge and appreciation of these classical researches have meant wealth to the brewer, the distiller, and the wine-grower; and it is hardly an exaggeration to say that the brewer of to-day is able to stand the relentless taxation of the late Chancellor of the Exchequer as much through the labours of Pasteur, and those who have succeeded him, as through the unquenchable thirst of the British proletariat. Extensive as were Pasteur's researches in the domain of fermentation, there were processes which time did not permit him to investigate before he was hurried on into other fields of scientific interest and practical utility. His intuition, however, led him to recognise as a fermentation process the transformation known as nitrification, consisting in the conversion of ammonia into salts of nitric acid, which takes place on such an extensive scale in all the fertile soils of the earth. This process, from being regarded as a case of simple chemical oxidation, is now recognised as dependent upon the action of bacterial life, and the particular bacteria responsible for this action, after long eluding the search of the investigator, have during the last few years been isolated and described. In the course of these researches the astounding fact has been brought to light that in these nitrifying bacteria we have living cells which are capable of flourishing and multiplying in the entire absence of organic matter

Digitized by Google

Even still more important revelations in vegetable physiology have resulted from the careful study of bacteria in recent years, for it has been shown that certain green plants obtain the nitrogen which they require for their nutrition from atmospheric nitrogen by means of certain bacteria which infest their roots. These bacteria produce nodular excrescences on the roots, but when they are carefully excluded these root nodules do not make their appearance and the assimilation of free nitrogen ceases also. The lecturer then referred to the recent important researches of Winogradsky of St. Petersburg on this subject, which have shown that under suitable conditions certain bacteria can take up this free nitrogen without the presence of the green plant at all. The intimate contact in which Pasteur had lived with the microscopic forms of life during his researches on fermentation—the great importance of which was recognised by the French Academy already in 1859, when they awarded him the prize for experimental physiology—naturally led him to take a deep interest in the controversy which was then raging on the spontaneous generation of life. Into this contest he plunged, despite the urgent protestations of many of his scientific friends, who feared that nothing would come of his venture but the loss of valuable time. It is now, however, admitted on all sides that the settlement of this question of such transcendent importance was finally accomplished by Pasteur through experiments as remarkable for their extreme simplicity as for their clinching force.

Professor Percy Frankland then reviewed Pasteur's connexion with the foundation and development of the infant science of bacteriology and his contributions to our knowledge of infectious diseases. Soon after he had commenced to study the bacteria of particular diseases he was impressed by the fact that often in the course of cultivation in artificial media outside the body their virulence became diminished to such an extent that they ceased to be fatal on inoculation into susceptible animals; but the most important discovery in this connexion was that the animals inoculated with such enfeebled or attenuated cultures were found to have become protected from the disease, even when subsequently inoculated with most virulent cultures of the same organism. This discovery at once enlarged the scope of Pasteur's investigations, which now included not merely the study of infectious diseases and their exciting causes, but embraced also the artificial protection of the individual against their attack. The most varied methods were devised and elaborated for attenuating viruses of different kinds, and multitudes of domestic animals were protected from some of the most destructive plagues with which they are afflicted. Pasteur next proceeded to grapple with a disease affecting both man and animals—viz., hydrophobia. This problem was surrounded with special difficulties, over which, however, the genius of Pasteur triumphed, and the attenuated virus of hydrophobia was successfully prepared and by several different methods. As a testimony to the faith which experience has built up in the efficacy of the treatment, we find centres for carrying it on in almost every civilised country in the world, whilst at the Institut Pasteur in Paris it is carried out on an enormous scale.

The great problem of securing immunity from disease, which thus occupied the later years of Pasteur's activity, has, however, now entered upon an entirely new phase. For, whilst Pasteur's methods depended essentially upon submitting the individual to be protected to the attack of the disease-producing organism itself in a weakened condition, the new methods of conferring immunity do not involve any contact whatever between the individual and the virus in any shape or form. The initial step in this new method of treatment was the discovery that the artificial cultures of pathogenic bacteria may be entirely freed from the micro-organisms and yet produce their characteristic poisonous effects; the symptoms of a particular infectious disease can be obtained through the injection of the toxic or poisonous products elaborated outside the body by the particular micro-organism associated with that disease. By this discovery the toxines of diphtheria and of several other diseases have been rendered as specific poisons as are laudanum or the extract of nux vomica. It was further found that animals can be gradually accustomed to these specific toxines, and the question then arose as to how such animals which had undergone this gradual habituation to a particular toxine would behave on being subsequently inoculated with the disease-producing organism itself. It was found that such animals were able to withstand or were protected from the attacks of such virulent bacteria. This important step we owe to the labours of Salmon, Roux, Chamberland, and other investigators. The next step was the discovery that the blood of an animal thus artificially protected from a particular disease contained materials which can be transferred to other animals and which protect them also from the same disease. This astounding property of the blood serum of artificially immunised animals was first discovered by Richet and Héricourt, but to Behring and Kitasato is due the credit of having first shown in the case of diphtheria and tetanus that by means of such serum animals may be cured even after the disease has been actually contracted, provided the injection of the antitoxic serum is not postponed until too advanced a stage of the malady has been reached. Again, to Behring is due the merit of having extended these benefits in connexion with diphtheria to man himself. The lecturer then referred to a diagram showing the diphtheria death-rates per million living in the principal cities of the United Kingdom during the years 1883–92 and 1893 respectively. In commenting upon these statistics it was pointed out how in London the figures had risen from 300 in 1883–92 to 760 in 1893, whilst in West Ham, virtually a part of London, an increase from 250 to 420 deaths from diphtheria had also been recorded. As indicating the value, so far ascertained, of the serum treatment of diphtheria he quoted Kossel's recent figures giving the mortality from diphtheria in Germany before the introduction of the new treatment as 34·7 per cent. and since its application as 11·1 per cent. A fact of great importance to be observed in this new treatment of diphtheria is the circumstance that its efficiency is greatly dependent upon the time which elapses between the first manifestation of the disease and the application of the curative serum. The shorter the period which intervenes the better are the results obtained, and this condition applies equally to the treatment of other diseases, such as tetanus, by means of antitoxic serum, whilst it has also been established as a cardinal principle by Pasteur in his treatment of hydrophobia. So great is the demand for the therapeutic serum for diphtheria that its production is already a commercial undertaking of some magnitude in Germany, where coal-tar colour manufacturers with their numerous staffs of skilled chemists have still further enlarged their works by undertaking the elaboration of diphtheria antitoxic serum on a most extensive scale. The possibilities of securing protection by means of the serum of immunised animals extend even beyond the boundaries of infectious disease, for Calmette in France and Fraser in Edinburgh have been able to gradually accustom animals to larger and larger doses of snake venom, and have found the blood serum of such animals endowed with the power of protecting other animals into which the venom is injected. When we remember, said the lecturer, that 20,000 of our Indian fellow-subjects perish annually from snake-bites, and that the new method of treatment extends the prospect of saving many if not all of these, it is obvious that we are here again face to face with a subject of stupendous importance, and which affects us above all the other nations of Europe. In conclusion, Professor Percy Frankland pointed out the widespread influence which Pasteur had exercised upon the progress of science during the latter half of the present century, and that this extraordinary influence, wrought in so many different departments of science, must be attributed in the first instance to the possession of a singularly active, clear, and original mind, matured under the strict discipline of an arly training in mathematics and the exact sciences, which enabled him to submit biological phenomena to a rigid, logical, and uncompromising criticism such as they had never previously received. But even this rare combination of natural and educational endowments would have availed but little had there not been united to them an almost superhuman industry, an almost limitless capacity for work. It would be difficult also to find a better illustration of the manner in which one science can benefit from contact with another than that which is furnished by the results which have attended the digression of the specially trained chemist into the fields of biology and medicine. To Louis Pasteur belongs the glory of having set in motion that great medical revolution which has been well sketched by a modern French writer. "When man learnt how to protect himself from the wild beasts he made the first step in civilisation. To-day man is learning how to defend himself from microbes; it is a step of equal importance. A day will come

Digitized by Google

when in Berlin, in London, in Paris, man will not die of diphtheria, of typhoid fever, of scarlet fever, of cholera, or of tuberculosis any more than he dies in these cities to-day of the venom of snakes or of the tooth of wolves."

SPASMUS NUTANS, OR THE NODDING SPASM.

BY GEORGE DICKSON, M.D. EDIN.,
FORMERLY RESIDENT MEDICAL OFFICER, EDINBURGH CITY POORHOUSE HOSPITAL, CRAIGLOCKHART.

THE following is a typical case of a somewhat rare disease — viz., spasmus nutans. The name "spasmus nutans" is somewhat misleading. Probably "spasmus oscillans" would be at once more descriptive and less confusing.

The patient, a boy aged one year, came under my care at Craiglockhart Poorhouse Hospital on Dec. 11th, 1893. No history was obtainable. On examination the child was found to be pale, but well nourished. There was only a slight appearance of rickets. There were two upper and two lower incisor teeth. The head was noticed to be constantly held inclined to the right side when the child was sitting up. In addition it shook from side to side in a way such as expresses dissent. The greatest excursion of the lateral movements was to the left, and there was a slight downward inclination, also to the left. The movements were not constant, but were induced or increased by excitement of any kind or by engaging the child's attention. Restraint of the movements caused marked discomfort. They entirely ceased during sleep and when the child was laid on his back. A day or two after admission horizontal nystagmus of the left eye was noticed. It also was only occasional, and was increased or induced by attempts at fixation, and markedly so by restraining the head movements. There was no impairment of vision or ocular movement, and the fundus oculi was healthy. The right pupil, however, was somewhat larger than the left. When looking at objects the child threw back his head, and, still keeping it inclined to one side, of necessity squinted at the object looked at instead of directing his gaze straight towards it. On Dec. 23rd the patient remained *in statu quo*. On Jan. 26th, 1894, the movements returned more markedly, and two teeth were observed to be cutting through the gums. On Jan. 29th there was slight return of nystagmus in the left eye, and slight nystagmus also of the right eye. About the middle of February another tooth cut through the gums and the nystagmus disappeared, the movements at the same time becoming less marked. On April 3rd the child to all appearance was quite well. In this case no treatment was adopted but the administration of cod-liver oil and attention to diet.

Since the above case came under my notice I have, through the kindness of Dr. John Thomson of Edinburgh, seen three others, and have been able from the books to collect full notes of twenty-three more, making twenty-seven in all. The literature on the subject is somewhat scanty. To Henoch of Berlin belongs the credit of having first drawn attention to the subject. In his text-book on Diseases of Children he gives in the first edition two cases and in the second edition four cases. In THE LANCET[1] Dr. Stephen Mackenzie gives two cases (Harveian Society Reports). In St. Bartholomew's Hospital Reports[2] two cases are recorded by Dr. Gee. In the Ophthalmic Society Reports[3] Mr. Nettleship records what appears to be an example of spasmus nutans. In THE LANCET[4] Dr. Hughlings Jackson mentions the affection in his address on the Relation of Ophthalmology to General Medicine, and suggests that it is akin to canine chorea. In the *Ophthalmic Review*[5] a case is quoted from Dr. Gordon Norrie of Copenhagen. The fullest account of the disease, however, will be found in THE LANCET,[6] in which the late Dr. Hadden gave full notes of five cases and an analysis of twelve. In St. Thomas's Hospital Reports for 1892 Dr. Hadden recorded nine other cases. Kassowitz, in an untranslated paper,[7] mentions spasmus nutans, classifying it among the nervous symptoms of rickets. The following five symptoms of the disease may be noticed: (1) head movements; (2) nystagmus; (3) petit mal; (4) strabismus; and (5) a peculiar way of looking at objects. The first two are by far the most constant. Both movements and nystagmus are present in about 90 per cent. of the cases, but at certain stages, or even throughout its entire course, the affection may be represented by only one of these. During incidence one—most frequently nystagmus—appears before the other, and during subsidence the nystagmus generally persists longest. The head movements are most commonly a combination of shaking and nodding. Pure lateral movement is very uncommon, and pure nodding extremely rare. In frequency the movements are about 20 per minute. They cease during sleep and when the child is placed on his back. They are increased or, if absent, excited by engaging the child's attention. They are not increased or induced by covering the eyes. Whether moving or not, the head is generally held inclined to one side, and there is generally greater excursion of the movement to one or other side. Restraint of the movements causes marked uneasiness. The nystagmus may be monocular or binocular, most commonly the latter. The nystagmic movements are very rapid, about 200 per minute. They are increased or induced by engaging the attention, and markedly so by laying the child on his back or by fixing the head. The nystagmus is only occasional, like the head movements. In direction it is most frequently horizontal, and only occasionally rotatory or vertical. Nystagmus of the eyelids sometimes occurs, and hippus has been noticed. With regard to petit mal, Dr. Hadden first drew attention to this fairly constant symptom. The child is simply observed to look vacant for a few seconds, and occasionally the head or the eyes, or both, deviate to one or other side. Strabismus is not nearly so common as the other symptoms. It may be constantly present or only occasionally. In some cases it is only noticed during an attack of petit mal. A peculiar way of looking at objects is nearly always observable. Dr. Hadden has happily described it as "looking out of the corners of the eyes." It is probably due to the head being held, when looking at objects, in that position in which its movements can best be restrained. The pupils are generally normal, but hippus has been noticed, and occasionally temporary inequality of the pupils has been observed. The fundus oculi is always normal and the vision perfect. The general health is nearly always good. The diagnosis is comparatively easy. Eclampsia nutans—the salaam convulsion—is only confusing in name. In this the whole upper part of the body participates in a forward movement which is distinctly paroxysmal. The movements of spasmodic torticollis resemble slightly those of spasmus nutans. Cases represented by nystagmus alone might be mistaken for other forms of nystagmus until the eyes were examined and no ocular defect discovered. The prognosis is always favourable. In any given case it would be safe to say that recovery will take place before the child is two years of age, and that in all probability it will take place very much earlier. It is not the forerunner of epilepsy, and the after intelligence of the child is in no way impaired. As to treatment, the affection has a natural tendency to recover without drugs. Bromides are recommended by Dr. Hadden, Dr. Thomson has found benefit from antipyrin, and Kassowitz recommends anti-rachitic treatment (phosphorus).

Remarks.—In considering the etiology of spasmus nutans it is evident that, while sex has probably no influence, age is a factor of the first importance. A comparison of the cases shows that 50 per cent. occurred between six and twelve months; 15 per cent. were under six and 15 per cent. over twelve months of age. The youngest was that recorded by Norrie, where the disease was noticed shortly after birth. Although Kassowitz looks upon the affection as due to rickets, this occurs in such a small proportion of the cases that it cannot be looked upon as more than an occasional predisposing cause. Convulsions, either as a personal or family tendency, are somewhat uncommon. Falls on the head are recorded in six or seven of the cases, the affection being noticed immediately afterwards. Dr. Hadden suggests that they may be more the result than the cause, being actually attacks of petit mal. It is possible also that anxious mothers, looking out after a fall for consequent mischief, have their attention first drawn to symptoms already existent. Dentition is,

without doubt, an important causative factor. The disease is one peculiar to the dentition period. Moreover, Dr. Thomson had a case where the symptoms began at three months, dentition also beginning at this abnormally early period. That it is not the only etiological factor involved is shown by the fact that the disease may appear when dentition is not active—e.g., two cases under one month. The nystagmus which occurs in coal-miners presents a somewhat curious analogy to spasmus nutans. In miner's nystagmus head movements occasionally occur in bad cases, and attacks of petit mal have been recorded.[8] The occurrence together of head and eye movements would point to a very intimate connexion between the cerebral centres presiding over these movements. This is further suggested by the close inter-relation which subsists between the two in a state of health, and by the compensatory action of either in certain paralytic conditions of the other—e.g., ophthalmoplegia externa. Moreover, it is well known that there is a special frontal centre presiding over the combined movement of head and eyes. In this connexion it is interesting to observe the almost invariable correspondence in direction of head-and-eye movements in spasmus nutans. Out of seventeen cases that can be compared this correspondence was present in fifteen. This includes one case where the nystagmus was vertical in one eye and horizontal in the other, the head movements being combined nodding and shaking, and a still more interesting and suggestive case where the nystagmus was generally horizontal, occasionally rotatory or vertical, and in which the head movements were usually shaking, but occasionally nodding. The disease is probably due to an instability of the ultimate elements of the brain substance in the region of the centre involved. This instability further evidences itself by the frequent occurrence of petit mal. Dentition must be looked upon as by far the commonest exciting cause, but it is probable that any other reflex irritation would—other things being equal—produce the same effect. In one of my cases, where there was no appearance of dentition, a probable reflex cause was a large irritable patch of eczema capitis, the cure of which was followed by subsidence of the symptoms. It must be remembered that about this period the whole nervous system is in a state of great irritability and instability, and it is scarcely surprising that the highly complicated mechanism involved in what are the first attempts at coördinated action tends to get out of gear from trivial causes.

I have to acknowledge my indebtedness to Dr. Edward Carmichael, visiting medical officer to the Edinburgh City Poorhouse, for much kindness in supplying me with literature and many valuable suggestions.

LAPAROTOMY IN TUBERCULOUS PERITONITIS.

BY GEORGE E. WHERRY, F.R.C.S. ENG.,
SURGEON TO ADDENBROOKE'S HOSPITAL, CAMBRIDGE; LECTURER ON SURGERY, UNIVERSITY OF CAMBRIDGE.

LAPAROTOMY and douching of the peritoneal cavity are proceedings too often described as "heroic," and are either never tried at all or only used as a last resource. One of the most striking cases of recovery I ever witnessed was that of a patient sent to Addenbrooke's Hospital under my care as suffering from obstruction of the bowel, vomiting and complete constipation being the prominent symptoms. It was judged to be a case of tuberculous peritonitis with many adhesions. The greatest success followed an operation in which purulent lymph and fluid were washed out of the abdominal cavity by free warm douches. There were many adhesions found, but no constricting band. A case quoted by Mr. Knaggs is similar.[1] As a more deliberate proceeding, and before the patient is in immediate danger, the operation may prove of great advantage. The following case is an example in which there existed disease in the chest, as well as most serious tuberculous peritonitis, with an unusual amount of fluid in the peritoneal cavity. Abdominal incision and washing out the peritoneal cavity gave excellent results.

A young woman aged nineteen years was sent for treatment under my care in Addenbrooke's Hospital by Mr. De Lisle in January, 1895, when it was noted that she had a good family history and had a healthy past life, not often ailing except for amenorrhœa and anæmia. During the past six months she had been invalided, and for the last three months had had a dry cough, with pain in the right side, which lasted three weeks and was followed by shortness of breath. The abdomen had gradually been growing bigger during about nine months. There was no blood spitting or night sweats. She was a fair girl with good teeth, but had been losing flesh lately. In the chest there were exaggerated breathing sounds on the left side. The right side was dull throughout, and breathing was diminished. There was no pectoriloquy. At the apex there was an occasional crepitus or crackle due to friction. There was no cough or expectoration. The abdomen was distended, bulging in the flanks. The dulness in the flanks extended half-way to the umbilicus, which varied with the position of the patient. There was a fluid thrill. No tumour was felt and no friction was audible. Pain and tenderness were very slight. The bowels were regular. The catamenia were absent. The specific gravity of the urine was 1020, acid; it contained phosphates, with distinct albumin. At the end of January Dr. Latham kindly consulted with me about her condition. The lung signs were most serious, and the circumference of the abdomen at the umbilicus was thirty-five inches. The patient grew decidedly worse, the abdomen painfully tense, and on Feb. 12th an operation was performed under an anæsthetic. Through a median abdominal incision (three inches) fifteen pints of fluid were evacuated. There was no evident pus or lymph; the whole of the peritoneal lining of the abdomen and bowels within sight or touch was thickly studded with tubercles varying in size from a pin's head to a pea. The right ovary felt like a nutmeg grater; no smooth surface could be found anywhere in the abdominal or pelvic cavity. Warm boric douching was used, and the wound was closed with sutures and covered as after ovariotomy. It was examined on the twelfth day and found to be healed, the patient's condition having already improved. The temperature, which had been usually up to 100° F. in the evening, became uniformly normal from the date of the operation. A certain amount of fluid collected again, but the patient improved so far that she could leave the hospital on March 23rd. Mr. De Lisle wrote to me on June 29th as follows: "I have delayed answering your letter, waiting to see what the result of time, following your directions, would be in the case of the patient upon whom you operated. I am extremely pleased to be able to tell you that the result is eminently satisfactory. Up to May the fluid in the abdominal cavity did not seem to lessen, and I was afraid I should have to send her back to you. With the advent of the fine warm weather early in May a marked improvement took place; the fluid seemed rapidly to disappear, sweating ceased, the cough lessened, and she began to gain flesh and strength. She is now her normal size, has no cough, has walked as much as ten miles in a day, and has gained weight. In fact, she describes herself as feeling 'quite well.'" On Sept. 3rd her progress to recovery was complete. She was 10 st. 3 lb. in weight, there being no active lung symptoms. The size of the abdomen was normal. She did her work, walked, danced, and led the ordinary healthy life of a girl of her age full of vitality.

Mr. Holmes[2] gives the experience of St. George's Hospital in seven years as three operations of laparotomy for tuberculous peritonitis and two deaths. The fatal cases were complicated in one instance by a band constricting the bowels and in the other by pneumonia. There was in the case I have just related an improvement in the general health after my operation which permitted an arrest of activity in the abdominal disease. We must not expect that patients will be cured when all the cavities of the body are full of tubercle, but every chance should be given to surgical procedure as a most powerful remedial agent in tuberculous peritonitis. It will be, perhaps, found that a case with a large quantity of fluid is most suitable for laparotomy; but this may be only because the fluid collects more in the earlier stage of the disease and adhesions mat together the bowels in more advanced cases. By laparotomy the fluid is thoroughly drawn off, and the tension is relieved, and whether douching is more than accessory to drainage it is difficult to say. Certainly tapping the abdomen alone makes

no such favourable impression on the disorder. Improvement in the general health may be expected to follow an operation, and so give a chance for the cure of other foci of tuberculous disease.

Cambridge.

A CASE OF IDIOPATHIC TETANUS FOLLOWING INFLUENZA; RECOVERY.

BY JAMES MILNER, L.R.C.P. EDIN., M.R.C.S. ENG.

FROM the fact that the percentage of recoveries from tetanus—either traumatic or idiopathic—is not large, and also from the existence of an unusual probable causation, the following case may be considered of some interest.

During the height of the influenza epidemic I was called, on the evening of Feb. 25th of this year, to see a man aged thirty-five years, with the usual symptoms of influenza, who had been complaining for several days. Upon asking the patient to protrude his tongue I noticed at the time—though I did not then put the correct interpretation upon the fact—that he opened his mouth with difficulty and did not separate his teeth more than just enough to show the tip of his tongue. Although he complained of stiffness of the jaws and neck, influenza seemed to be a sufficient explanation, and tetanus did not occur to me until I saw the patient by daylight on the following day (Feb. 26th), when the presence of a "risus" and the patient's statement that he had "striking" pains in his back and legs led me up to a suspicion of the true nature of the case, which became a certainty when upon the patient attempting to comply with my request that he should separate the teeth as far as possible a well-marked tetanic spasm took place. The case ran the usual course. The jaws became tightly closed, so that only fluids could be administered. The spasms increased in frequency and violence, although fortunately they were never of long duration, the most severe one witnessed by me not lasting more than sixty or seventy seconds in its full intensity. The abdominal surface was as hard as a board. The legs were rigid, and the arms slightly so, the right much more than the left, which was only very slightly affected. By March 1st the spasms had attained their full intensity, and remained extremely severe until the 10th, after which date they gradually declined. The complications (which gave no anxiety) were: (1) retention of urine on two or three occasions, but not so urgent or prolonged as to demand catheterism; (2) some redness and tenderness of the heels, evidently from pressure; and (3) a vesicular eruption confined to the back and sides of the neck. This latter I could not satisfactorily account for. There was at the same time a papular bromide rash over other parts of the body, but this very closely aggregated vesicular eruption (which here and there became pustular) was confined to the back and sides of the neck. The only sequela was an attack of subacute synovitis—probably rheumatic—in both knee-joints, which somewhat retarded recovery, but which fortunately did not appear until almost all tetanic spasm had departed. Briefly, the treatment consisted in the administration of bromide of potassium and morphia in quantities large enough to keep the spasms within tolerable limit, and in maintaining the strength as well as possible by suitable nourishment. The largest amount of bromide given was 180 grains (in divided doses), and of morphia 3 grains in a single dose at bed-time. These were the largest amounts of the drugs given in any one period of twenty-four hours, and only when the frequency and severity of the spasms had overcome smaller doses. As the violence of the spasms abated, the medicines were gradually diminished until March 24th, after which date all bromide was stopped, and salicylate of soda with ammonia was given for the rheumatism. An occasional opium pill had still to be administered at bed-time for the pain of the latter complaint, but nothing more was required for the tetanic spasm. On May 1st the patient was of course suffering from debility, and a joint ached occasionally; but he could walk a couple of miles without undue fatigue.

Remarks.—I have not seen influenza mentioned as a cause of tetanus, but from the absence—to my mind—of any other explanation I cannot help thinking that it was the etiological factor in this case. The weather had been unusually cold, but the low temperature had been continuous, and this is, I believe, acknowledged not to be nearly so potent in the causation of tetanus as sudden vaiations of temperature. The man had certainly been exposed to cold and damp, but so he had during the whole of his life, and he had never before been ill for a single day. There was no history of any injury, and a close search revealed no wound or even scratch of any kind.

Shipdham, Norfolk.

THE PREVENTION OF PUERPERAL FEVER.

BY J. MCNAMARA, M.D., B.CH., B.A.O. R.U.I.

I INCLUDE under the heading "puerperal fever" diseases of the puerperium which are represented in ordinary surgery by (1) pyæmia, (2) septic infection, and (3) septic intoxication. Septic intoxication in the puerperal state can generally be arrested by judicious douching, but the treatment of septic infection and pyæmia is all but hopeless. It is not, however, with the treatment of these grave conditions that I am now concerned, but with their prevention. This is a subject on which very little that is novel can be said. It is a subject which has been discussed again and again in the pages of the medical press, and my only excuse for bringing it forward once more is that, although puerperal fever is a preventable disease, it is not at all an uncommon one. In other words, every year and every month, through ignorance or through negligence, patients are invalided who should be well, or lives are lost which should be saved—a fact which, I venture to say, registrars and coroners might well take cognisance of in the interest of the community. "Whatever indulgence," said Oliver Wendell Holmes, "may be granted to those who have heretofore been the ignorant cause of so much misery, the time has come when the existence of a private pestilence in the sphere of a single physician (and, I would add, of a single midwife) should be looked upon not as a misfortune but a crime; and in the knowledge of such occurrences the duties of the practitioner to his profession should give way to his paramount obligations to society." If anyone should think that these words of the genial and kindly Holmes are characterised by undue asperity, I would ask him to place his own wife or his own daughter in the position of the patient and then picture to himself the ignorant or the negligent attendant hovering round the bedside with "death in his finger-nails."

To prove the value of the following plan for preventing puerperal fever I need only mention that in the course of some 300 deliveries in which I adopted this plan not one mother has died, not one has developed a septic symptom. Results like these are, I believe, unknown except in antiseptic midwifery. The first thing then, is to provide a supply of powders or tabloids, each containing ten grains of corrosive sublimate with ten grains of ammonium chloride. One of these powders or tabloids when added to a pint of water will make a solution of corrosive sublimate of about 1 in 1000. If the powders be used it will be found that in most of the ordinary waters which (like the London water) contain lime salts, the corrosive sublimate gets decomposed, the mercury is liberated, and the solution becomes opalescent. To prevent this the addition to the solution of a pinch of tartaric acid will suffice. Before examining the patient internally the hands should be well washed with soap and warm water and then kept in the corrosive sublimate solution for at least two or three minutes. It is commonly advised to make vigorous use of the nail-brush before washing the hands, but the average nail-brush in the average house is, I believe, more septic than most hands. I think, therefore, that the judicious use of a clean pocket-knife, followed by washing and disinfecting in the sublimate solution, more advisable. The hands should be left at least two or three minutes in the solution. It is true that a solution of corrosive sublimate of the strength of 1 in 1000 is capable in about fifteen seconds of killing or of rendering harmless the most virulent of the organisms which cause puerperal fever, but it is well to allow time for the solution to reach at least the superficial parts of the hair follicles and gland orifices of the skin. In making the internal examination the hands should be introduced directly from the solution without previous drying in probably septic towels. If a lubricant be required

Digitized by Google

carbolic oil (1 in 8) will give every satisfaction. The glycerine solution of corrosive sublimate, which has been frequently recommended as a lubricant, I find useless when the hands are wet, for the glycerine so mixes with the water as to lose its lubricating power. So much then for the hands, and now as regards the vulva. The vulva, from its warmth and from its moisture with organic fluids, is a veritable culture ground for micro-organisms. It should, therefore, be disinfected by being well mopped with the corrosive sublimate solution whenever it is necessary to introduce any instrument or the whole hand or more than one finger. I say more than one finger, for when, as in the ordinary examination, it is only necessary to introduce the index-finger, this can be so shielded by the other fingers as to be prevented from rubbing against the parts, and so saved from the danger of introducing septic matter. In ordinary cases, therefore, although it may be advisable, it is not necessary to disinfect the vulva. As regards the instruments, when these are needed I find that the best and most convenient way of disinfecting them is by boiling. There is no difficulty about this. An ordinary kettle or an ordinary pot, filled with water and boiling on a fire, is all that is required. Take, for instance, the forceps, which is the instrument most commonly required; the handle half can be first dipped into the kettle or pot and left to boil for four or five minutes; then, by holding a clean napkin in the hand, the instrument can be inverted and the blade half left to boil for four or five minutes more. Then the instrument can be removed, placed on a clean napkin, and when sufficiently cool lubricated on its convex surface with carbolic oil. While the instruments are being boiled the vulva can be disinfected. If a little of the corrosive sublimate solution be preserved and subsequently diluted to about 1 in 5000, it will be found of the highest value for cleansing the infant's eyes and thus warding off the danger of purulent ophthalmia.

I have now dealt with the hands, the vulva, and the instruments, and it only remains to say a few words on the advisableness of douching after delivery. When the whole hand or any instrument has been introduced into the uterus, or if during the week after delivery there should be any serious rise of temperature, I believe douching with a solution of corrosive sublimate (1 in 5000) advisable. In other cases I think douching should be dispensed with. Routine douching after delivery I believe to be bad practice. It is a little operation which has certain dangers and inconveniences of its own, and why should these be incurred when the patient is going on all right and when there is no reason to fear that she may not continue so? But whenever douching after delivery is thought advisable the medical man should do it himself and not leave it to a nurse, who will probably fail to introduce the tube into the uterus.

I will conclude by apologising for the small and apparently trivial details I have given. Although small, they are details on which momentous issues—issues of life and death—depend, and their adoption will, I am convinced, save others, as they have saved me, from that most painful of spectacles, that saddest of tragedies—the death of the patient through the fault of the attendant.

Milson-road, W.

DIFFICULTIES WITH THE ELECTRIC LIGHT IN BRISTOL.—Some inconvenience has been caused in Bristol by the uncertain character of the electric light and by its liability to sudden extinction at inconvenient times. On the afternoon of Sept. 23rd, whilst a cable was being tested, smoke issued from the manhole leading to a sub-station chamber under the pavement, and on the cover being removed flame and dense smoke arose, apparently due to the overheating of metal in contact with creasoted wood. The light was, however, supplied in the evening as usual.

PROSECUTION UNDER THE PUBLIC HEALTH ACT.—At the petty sessions held at Thorpe on Sept. 23rd a woman was fined the mitigated penalty of £3 for having on Aug. 9th removed her daughter aged thirteen years, who was suffering from diphtheria, from Clacton to Colchester by railway, the alternative in default of distress being twenty-one days' imprisonment. The defendant, who is in humble circumstances, argued that the illness was quinsy and not diphtheria; but Mr. T. G. Wakeling of Clacton, who had been in attendance on the case, and Dr. J. W. Cook, medical officer of health of Clacton, proved that the patient suffered from diphtheria, and that they had warned both her employer and the defendant that she was not to be removed.

LONDON HOSPITAL.

A CASE OF DOUBLE PHLEGMASIA ALBA DOLENS IN A YOUNG VIRGIN, HEALTHY EXCEPT FOR SLIGHT ANÆMIA.

(Under the care of Dr. HERMAN.)

CASES of extensive thrombosis are not frequently seen in the wards of our hospitals, and the description of the following case will be read with profit by many engaged in the study of medicine. It is difficult to account for the occurrence of such an extensive clotting as was undoubtedly present here, where but for a slight amount of anæmia the patient was apparently in good health. Dr. Vaquez[1] of Paris believed that "white leg" is but the second stage of a complication of infectious nature. The first stage, from a clinical point of view, is characterised by pain, elevation of temperature, and transitory œdema, the latter being especially prominent in cases in which the pain is so acute as to be called neuralgic; from a pathological standpoint, by the formation of a thrombus in the vein; and from a bacteriological standpoint, by the detection of the infectious agent, which most often is the staphylococcus. We think it is rare to meet with thrombosis of veins of obscure origin in young women who do not present evidences of anæmia. For the notes of the case we are indebted to Mr. W. Penberthy, resident accoucheur.

A young woman aged twenty, single, was admitted into the London Hospital, under the care of Dr. Herman, on Nov. 1st, 1891, complaining of pain and swelling of the left thigh, leg, and foot. She stated that she had menstruated regularly every month, having last been unwell three weeks before admission; until now she had always had good health. A fortnight before admission she was attacked by pain in the back and extending down the back of the left thigh. This pain was so severe that she had to go to bed. A week before admission the pain ceased, but the limb began to swell rapidly, attaining its maximum size in twenty-four hours. On Nov. 2nd the left thigh was greatly swollen, measuring 26½ in. round at its upper part, the right at the same level measuring 20½ in.; the leg and foot were also swollen, but not so much in proportion as the thigh. The limb was hot and tender to the touch. No thrombosed veins could be distinguished. There was no pitting on pressure of the thigh, nor did serum exude on pricking it, but the foot both pitted and exuded serum when pricked. The left labium was also swollen, and there was some tenderness on pressure over the left iliac region, though nothing abnormal could be felt. The patient was a well-nourished, healthy-looking girl, slightly anæmic. The heart and lungs were sound. The urine was acid and contained no albumin or sugar. The temperature was 102° F. The blood contained 50 per cent. red corpuscles and 46 per cent. hæmoglobin; the white corpuscles were in about the normal proportion. Under treatment the condition at once began to improve, the limb becoming less painful and tender, pitting on pressure, and gradually diminishing in size. On the 10th the temperature became normal. The left limb went on uninterruptedly to recovery. On the 15th the temperature rose to 100°, and to a degree higher the next day, when it was noticed that the right thigh was beginning to swell. On the morning of the 17th the circumference of the right thigh was 26 in. at the place where it had previously measured 20½ in. Subsequently followed swelling of the right labium, leg, and foot, and tenderness on pressure over the right iliac region, and after a few days gradual diminution of the symptoms set in. No distinct thickening of superficial veins could be felt. On Dec. 16th Dr. Herman made a vaginal examination, and found the

[1] Sajous: Annual of the Universal Medical Sciences, vol. iii. 1893, p. 14.

Digitized by Google

uterus movable but not enlarged; there was no parametric swelling, and nothing abnormal could be detected. There was nothing in the condition of the genital organs to suggest the slightest doubt of the patient's virginity. Dr. Stephen Mackenzie saw the patient with Dr. Herman, but found no disease other than that which has been described. The patient was discharged on Jan. 4th, 1892. She returned on Feb. 9th because the swelling of the legs had recurred, though not to the same extent as before. She was admitted and remained in the hospital till May 7th. The œdema went away, and the legs ceased to ache when the patient was recumbent, but they never returned to what had been their size before the illness; some solid œdema remained. Elastic bandaging was used, but the greatest effect on the pain and swelling seemed to be obtained by enveloping the limb in Scott's dressing. In spite of all treatment the legs remained much thicker than before the illness, and the patient could not stand or walk long without their aching and becoming œdematous.

Remarks by Dr. HERMAN.—The above case is published because it is one of extreme rarity, which, by its exceptional features, negatives some ill-founded theories as to the nature of the disease. Every student knows that phlegmasia alba dolens is usually a puerperal disease. But it is not common even after parturition; and not every case of swelling of the leg or legs in puerperal women presents the non-pitting œdema and other characteristic features of phlegmasia dolens. Some think that it is due to septic poisoning or to some blood poison gaining access by means of injury to the genital canal during delivery. This view I do not think in accordance with facts. Next in frequency to the puerperal state as recognised causes of white leg come the cachexias associated with advanced cancerous or tuberculous disease. In this case all the characteristic features of phlegmasia alba dolens were well marked, although the patient was a young virgin, healthy in every respect except for a slight degree of anæmia; there had been no opportunity for septic or any other wound infection.

ANCOATS HOSPITAL, MANCHESTER.

TWO CASES OF RECTAL CARCINOMA; PRELIMINARY COLOTOMY IN ONE; EXCISION; RECOVERY.

(Under the care of Mr. E. STANMORE BISHOP.)

DURING the last twelve months three cases of rectal stricture have been treated in Mr. Bishop's wards: one, a case of simple stricture, by dilatation; the other two (due to carcinoma) in the one case by partial and in the other by total excision of the rectum. All three cases ended in recovery. The two latter are given in detail. They represent two of the modern methods of operation for cancer of the rectum. In both recovery followed, and it is probable that the result attained in these cases is more frequent than it was a few years ago. Some published statistics[1] on this subject are of interest. It appears that during thirteen years there were 109 cases of cancer of the rectum operated on in the wards under the care of Czerny. In ten cases death followed the operation. Of the remaining patients 21 per cent. lived two years, 15 per cent. three years, 13 per cent. four years, and 8 per cent. five years, while four others were living more than six, eight, eleven, and thirteen years after the operation. Forty patients had survived the usual three years' limit. Thirty-six cases were subjected to the sacral operation, and the rest to the perineal method. The second patient was unusually young for the presence of cancer, but in this situation it has occasionally manifested itself at a very early age. There was recently a case of advanced carcinoma of the rectum under treatment in one of the London hospitals in a girl aged fifteen years.

CASE 1.—A man aged fifty-eight years was admitted to the hospital on Aug. 18th, 1894. Nine months previously he had been admitted with a rectal polypus diagnosed as adenoma springing from the anterior wall about two inches above the anus. It was sessile. The rectum was dilated, and the polypus with its base was excised by an incision semi-circularly in front of the anus, the mucous membrane being separated and drawn down. In view of the close connexion between simple adenoma and malignant adeno-carcinoma in this region the patient had been placed under Dr. Carne Ross's treatment, and three months later examination showed an apparently perfect result, everything being smooth and flexible. He returned to work on May 1st, 1894. On re-entering the hospital he stated that he had been quite well and working until five or six weeks before, when he noticed that he was passing blood with his fæces, and that during the last three weeks there had been discharges of blood and mucus apart from defecation. There was no pain, but very frequent action of the bowel. On examination per rectum a hard mass was felt anteriorly, blocking the rectum and bleeding when touched. The surface was rugged. It extended for about one inch in a vertical direction about two inches above the anus, but its upper extremity was within reach of the finger. Below and above it the mucous membrane was smooth and elastic. On Aug. 21st the rectum was split posteriorly by an incision reaching to the tip of the coccyx. The growth was then removed by scissors and the wound was packed with gauze around a large rubber tube. This was changed on the fourth day. On Sept. 8th the wound was granulating well. There were incontinence of fæces and some diarrhœa. On the 14th all had healed. The mucous membrane was smooth as far as the finger could reach, except for a slight puckering in front and to the left side. He was again placed under Dr. Carne Ross's treatment. On Oct. 2nd the line of internal scar, though smooth, presented three nodules, which felt hard. There was no bleeding on examination. Defecation was easy, but there was still some incontinence of fæces, and the bowels were loose. The temperature reached 99·6° F. on the evening of the day after operation, but fell to normal the next day and continued so throughout. On Jan. 13th, 1895, the patient, who, feeling very well, had neglected to follow out Dr. Ross's treatment, returned, having noticed blood in his stools. On examination a hard patch was felt on the left side, about three inches from the anus, one inch and a half wide and one inch in vertical measurement, movable, bleeding on touch, and ulcerated on the surface. On the 15th, the sphincter being dilated, the mass was removed with scissors, together with a wide margin of healthy mucous membrane. Its base was not adherent and came away easily. There was very free hæmorrhage, and also there was some collapse during the operation, so forceps were left on all visible bleeding points, and the cavity left was plugged with gauze. He required the catheter for thirty-six hours, when the bladder acted naturally. There was some bloody oozing. The forceps and plugs were removed in forty-eight hours. The temperature reached 101° on the 16th. After this boracic irrigation was practised daily. On the 31st several large furuncles showed on the hip and thigh. These were incised, and the temperature, which had risen to 103·4°, fell to normal. On Feb. 10th the cavity had filled up and healed. The finger only felt a smooth ring of cicatrisation on the line of removal. There was no thickening or hardness anywhere. He was discharged well on Feb. 22nd. On Aug. 17th his wife reported that he was again at work, feeling well and gaining flesh. The incontinence of fæces was much less.

CASE 2.—A young man aged twenty years was admitted to the hospital on Nov. 30th, 1894. He had been sent to hospital twice complaining of the passage per rectum of blood and mucus, and of frequent and imperative defecation. He said that after a short preliminary rumbling in the abdomen the bowels would act very suddenly, expelling blood and mucus. Up to February, 1894, he had been perfectly well. His mother was living, aged fifty-two, as well as his father, aged fifty. One sister was dead, from a cause unknown. Two sisters and one brother were living and well. There was no family history of syphilis or carcinoma, and no personal history or evidence of syphilis. He had been treated for the latter. On examination per rectum there was found, one and a half inches from the anus, a stricture fully one inch long, hard, gristly, with nodulated opening, and admitting the little finger with difficulty. The lower segment of the rectum was healthy. He had passed blood last on Nov. 28th. On Dec. 3rd it was noted that the bowels had been moved daily since admission, without blood, the stools being of the thickness of the little finger and broken. On the 14th the rectum was dilated under chloroform. The stricture showed a reddened, nodular, crescentic rim projecting into the lumen of the gut. A small piece was removed for examination and under the microscope showed the structure of an adeno-carcinoma. On the 21st inguinal colotomy was performed. As there was much abdominal distension

[1] Lövinsohn: Sajous' Annual of the Universal Medical Sciences, 1894, vol. iii., E 10.

Digitized by Google

the gut was immediately opened and a large rubber tube passed upwards, which was stitched to the small opening made in the bowel. There was a large passage through this of thin fæces, followed by subsidence of the abdomen. On the 23rd the tube was removed and the surplus gut cut away. The edges were stitched to the skin by continuous silk sutures and painted with Whitehead's solution of iodoform. There was some passage of fæces per anum. He slept well and took milk diet freely. On the night of the 28th the temperature was 103·4° F. and 100·4° on the following morning. An ulcer had formed at the upper end of the colotomy wound and was touched with nitrate of silver. The temperature became normal on Dec. 31st and had remained so up to Jan. 8th, 1895, on which day Kraske's operation for excision of the rectum was performed. The rectal growth had greatly extended, and had so blocked the lumen of the gut that the finger could not now be passed. The coccyx and about an inch and a half of the left half of the sacrum were removed—in all, about three inches of bone. There was great difficulty in dissecting the mass free in front from the bladder and behind from the sacrum, to both of which it was closely adherent. When loose all round it was clamped above by two large pairs of angled forceps and cut away below. This was done partly because the patient was by this time suffering greatly from shock, and partly because the separation had to be carried so high that it was doubtful whether hæmorrhage could be sufficiently quickly controlled by any other means. The anus and healthy mucous membrane below had previously been separated, with the idea of uniting them to the upper part of the rectum after removal of the diseased portion, but the amount removed—about five inches—rendered this impossible. During the dissection the peritoneum was opened and closed by a stitch. The large cavity produced, the size of a child's head, was packed with iodoform gauze. The temperature rose on the 9th to 100·6°, on the 10th to 101·4°, and reached 102° on the evening of the 14th, after which it slowly fell. The forceps were removed on the 10th. On the 17th the cavity was found to be covered with pinkish granulations. There was much difficulty in keeping the wound free from fæces, although the inguinal opening acted well, and the upper end of the lower segment of the bowel was plugged with gauze. The patient looked hectic, but was taking food well. The sister of the ward, Sister Robinson, deserves great credit for the care she took to ensure the thorough cleanliness of the wound, which necessitated frequent irrigation and most constant attention. On Feb. 3rd the patient was much emaciated, but the cavity was contracting well and now measured 5 in. by 3 in. and in parts by 1½ in. The surfaces and edges were lined by healthy granulations. The fæces still passed through the wound in diminishing quantities. It was dressed with boric glyceride. Urination had never given any trouble. On the 17th the sacral wound was found to be steadily contracting. The hip on the left side appeared to have fallen in slightly. Fæces still passed in spite of the gauze plug. On the 24th the fæces had ceased to pass through the sacral wound, which felt perfectly smooth and was closing up rapidly. The patient was greatly emaciated. There was no enlargement of the liver or the spleen. On March 12th the patient's weight was 8st. 6½lb., and on the 23rd 9st. 1lb. On the latter date the wound was one inch long and looked perfectly healthy. There was much prolapse of the mucous membrane in the colotomy opening. On the 29th, as the patient was greatly improved in condition, the mucous membrane of the bowel was divided transversely a little below the centre of the colotomy wound, stripped up from the interior of the lower segment for nearly three inches, and removed. The muscular wall of the gut was then stitched together with silkworm gut, and the remaining mucous membrane was united to the skin around, a small drainage-tube being left. There was some pain for two hours, followed by "jumping" pains at intervals for two days. The drainage-tube was removed on April 1st. The temperature had risen to 102° on March 30th. On April 4th there was no pain, except some aching on movement. There was no pain on defecation. The temperature had come down steadily to normal since March 30th. A small slough and three stitches were removed. On the 28th the patient was found to have steadily improved. The posterior wound was quite dry but not yet closed. The colotomy wound had almost healed. His weight was 9st. 6½lb., and on May 1st it was 9st. 6½lb. The finger when passed per anum touched a pinhole opening by the side of the sacrum. There was no cavity beyond. The surface was puckered but smooth. The mucous membrane of the colotomy wound still prolapsed a little. The bowels acted well, but there was no control over their action. The patient was very useful in the ward. On Aug. 23rd there was no sign of recurrence. All had soundly healed.

Reviews and Notices of Books.

Surgical Pathology and Therapeutics. By JOHN COLLINS WARREN, M.D., Professor of Surgery in Harvard University. London: F. J. Rebman and Co. 1895. pp. 832. Price 42*s*.

FEW indications show more clearly the immense advances in pathology made within the last few years than the space assigned to bacteria in the ordinary text-books. Up to a comparatively recent date treatises on surgical pathology devoted only a few pages to the consideration of micro-organisms and their effects upon the body. The space thus employed has steadily increased, and now in many works the chapters devoted to these subjects form no inconsiderable portion of the whole volume. Dr. Warren gives two chapters (seventy-eight pages in all) to bacteriology. In the first he describes bacteria in general, and in the second he considers those which are of special importance to the surgeon. Descriptions are given of the various methods employed for studying bacteria, and coloured illustrations of tube-cultures and coverslip preparations accompany the accounts of the several micro-organisms. Succeeding chapters are devoted to simple and infective inflammation and the process of repair. The question of the possibility of pus arising apart from the influence of bacteria is discussed, and the conclusion arrived at is that though it is possible for pus to arise without bacteria, such an occurrence is extremely rare. Chapters follow on the ordinary "surgical" diseases, and in one respect this book differs from the majority of works on this subject. Usually the question of treatment is left out of consideration in treatises on surgical pathology, but Dr. Warren has attempted, as he tells us in the preface, to associate pathological conditions as closely as possible with the symptoms and treatment. Certainly there are advantages in considering the pathology and treatment together, for all modern treatment depends on our knowledge of the pathology. The work is well up to date. As a proof of this we may instance the description of the employment of tetanus antitoxin and the discussion as to the presence of micro-organisms in carcinoma. Very few errors seem to be present. It is, however, certainly a mistake to connect rachitis by derivation with ῥάχις; and on page 599, by a misprint, gluten appears to be a constituent of bone. We must praise the illustrations, some of which are in colours and many tinted, though often the tinting is more ornamental than useful. The printing and paper are excellent, and a good index is supplied. The whole work has been very carefully written and is a worthy representative of American pathology.

The Anatomy of the Nasal Cavity and its Accessory Sinuses: an Atlas for Practitioners and Students. By Dr. A. ONODI, Lecturer on Rhino-Laryngology in the University of Budapest; translated from the second edition by ST. CLAIR THOMSON, M.D., M.R.C.P. Lond., F.R.C.S. Eng. 1895. London: H. K. Lewis.

IN 1893 Dr. Onodi of Budapest published an atlas of twelve plates prepared from a series of sections showing the topographical relations of the nasal cavity and its accessory sinuses, especially with regard to the neighbouring organs, such as the eye and the ear. In the next year another

Digitized by Google

edition was called for, and four new plates were added. It is this second edition which has been translated by Dr. St. Clair Thomson. We may at once say that the engravings are most accurate and reach a high standard of excellence. They show sagittal, coronal, and horizontal sections and give a thorough idea of the anatomy of the nose, and the explanation of the individual plates is quite adequate. In a general introduction an account is given of the nasal walls and cavities, which is very clear and accurate, except that in describing the outer wall the lacrymal bone is omitted, although it is figured in the first plate. Although intended for practitioners and students, most of the sections really illustrate important relations which must always be present to operators, whether general surgeons or specialists, who have to deal with diseases of the nose and to whom an accurate knowledge of its topograpical anatomy is imperative.

La Pratique des Opérations Nouvelles en Chirurgie. Par A. GUILLEMAIN, Prosecteur à la Faculté de Médecine de Paris. Paris: Baillière et Fils. 1895. pp. 334.

IT is always a difficult matter for a text-book on general surgery to keep up with the rapid advance of the science. It is more than difficult—it is impossible. The successive editions of a text-book can appear only at distant intervals, and, moreover, it often happens that even while the book is in the press some part of it is out of date. The little volume before us supplies a decided want. It affords us that information about recent advances in operative surgery for which we might search in vain in any treatise on surgery published before the present year. We know of no such book in English. The work deals with the surgery of all parts of the body, but as greater activity has been manifested recently in abdominal operations, naturally these receive rather more attention than might otherwise be accorded to them. In this connexion we may mention that a good account is given of Murphy's button. The descriptions given are sufficiently explicit to enable a surgeon to perform the operations, but from the size of the book the accounts must be necessarily brief. Numerous references are given to papers and articles, but, as we might expect, they are for the most part French. Many illustrations are present and assist the text.

Poisons: their Effects and Detection. By ALEXANDER WYNTER BLYTH, M.R.C.S., F.I.C., F.C.S., Barrister-at-Law. Third Edition, revised and enlarged, with tables and illustrations. London: Charles Griffin and Co., Ltd. 1895.

A REVISED and enlarged edition of Mr. Wynter Blyth's "Poisons" might have been easily anticipated as soon as it was known what a valuable contribution on the subject he had placed at the disposal of the toxicologist and others some years ago. We are glad to find that the same general plan of the original has been preserved in the present edition; but, of course, to be in accordance with the enormous developments which recent investigation has been productive of, and of the ever-widening field which the constant addition of new toxic substances is opening to view, a great part of it has been re-written, enlarged, and corrected. Not less during the same period has been the advance in analytical methods of detecting poisons; old processes have consequently made way for new and—as experience has shown—more accurate ones. We like the plan and arrangement of this work, and the classification adopted makes the task of reference light. The introductory chapter on "The Old Poison Lore" is full of interesting historical reading, and is followed by a short but very instructive section on the connexion existing between the chemical structure of the molecule of organic substances and physiological effects; but the results obtained are, as it is observed, "too fragmentary to justify any great generalisation." In the succeeding chapter on life tests we venture to think that an error of judgment has been made. The author has purposely omitted to describe, as was the case in former editions, the manner of applying life tests because "the Vivisection Act effectually precludes the use of life tests in England save in licensed institutions." Nevertheless, a description of biological methods might have been retained, we think, for the benefit of those authorised to experiment upon animals for this purpose, while students and others should, at any rate, be acquainted with the way these things are done if they are not permitted to do them. This observation is also surely justified, since the effect of injecting animals with various poisons is fully described elsewhere, under the heading of "Action upon Animals," in the sections in which the poisons are separately discussed. The chapter on the cadaveric alkaloids or ptomaines or toxines is short, and they are, perhaps, not treated at that length which the increasing importance of the part these bodies are taking in disease and as poisonous agencies occurring sometimes in food, &c., demands. It is, however, thoroughly practical, and the work is essentially one for the searching analyst.

In regard to those ptomaines in particular which are said to have been isolated and crystallised from the urine of patients suffering from various diseases we must express ourselves in full accord with the author's remarks when he says that "to specifically declare that a few milligrammes of a substance is a new body requires immense experience and great skill, and even when those qualifications are present this is too often impossible, and, this being so, the long list of named ptomaines, such as erysipeline, varioline, and others, must have their existence more fully confirmed by more than one observer before they can be accepted as separate entities." The processes that have been described for the isolation of these products have appeared to us to offer no great difficulty of manipulation or experiment, and we wonder that other observers have not been induced to repeat the experiments, with a view of confirming or disproving the results affirmed to have been obtained. It is hardly necessary to speak in terms of praise of Mr. Wynter Blyth's work, as we know it is valued and largely trusted. We welcome the fact that it has recently been harmonised with modern advance. The excellent practical directions laid down are doubtless largely dictated by the result of experience and if carefully and intelligibly followed should leave no uneasy doubt in the analyst's mind as to whether he has missed what he is searching for, or whether or not to accept the indications of negative reactions. As a practical guide to the detection of poisons we know no better work of reference.

LIBRARY TABLE.

The Brewing of Non-Excisable Beers. By. J. POCOCK. Bangor. 1895.—The aim of this little work is to point out the principles upon which all non-excisable fermented beverages should be made, and to impart to those who do not know a knowledge of the processes which otherwise they blindly superintend. In this the author has succeeded fairly well; he has written some intelligible chapters on fermentation, the selection of yeast, the use of preservatives, &c., each of which should amply repay the perusal of the aspiring non-excisable brewer. We commend this little book because its object is to rescue an important branch of manufacture from the practice of haphazard processes, and to place the general production of non-excisable and wholesome beverages upon a more scientific and satisfactory basis.

Chemical Laboratory Labels. Part 2. Compiled by W. H. SYMONS, F.I.C. Published by A. Gallenkamp and Co.,

Digitized by Google

2, 4, and 6, Cross-street, Finsbury, London. 1894.—We have received a copy of Part 2 of this really useful collection of labels for the laboratory. The nomenclature is "up to date," and the addition of the formula and formula weight of the substance indicated is an obviously convenient one. The labels include a table of atomic weights and a print of Lothar Meyer's grouping of the elements, which, when fixed on a bottle or cylinder of such a diameter that both ends will meet, exhibits the elements periodically arranged on a spiral.

Introduction to the Study of Biology. By B. LINDSAY. London: Swan Sonnenschein and Co. 1895. 6s.—As an introduction to the study of zoology this book will doubtless soon become popular among students commencing the science, as it is especially written with a desire to meet the difficulties and requirements of beginners. The first part of the book deals with the general principles of biology. In an elementary work of this kind it would, of course, be impossible to go very far into such extensive questions as embryology, distribution of animal life, origin of species, and so on; but the author has succeeded in making an interesting and readable sketch of these principles, after the perusal of which those requiring deeper knowledge will the more easily understand larger works. The second part of the book is systematic, and consists of a classification of the animal kingdom, with the salient features of the different classes clearly pointed out and illustrated by numerous diagrams. There is a chapter which advises the student concerning his practical work, and also points out the chief standard works. Last, but not least, there is a glossary of the scientific words used in the book in which their derivations and meanings are fully given.

The Origin of Plant Structures by Self-adaptation to the Environment. By the Rev. GEORGE HENSLOW, M.A., F.L.S., F.G.S. London: Kegan Paul, Trench, Trübner, and Co., Limited. 1895.—The author considers that the origin of species depends chiefly on the environment and much less on natural selection than supposed by Darwin. The answer to the question, "What, if any, aid does natural selection supply in the origin of species?" depends upon the question as to whether the environment induces indiscriminate or, as Darwin called them, "indefinite" variations, and the author's reply is that a new environment does not, in any sense of the term, "select" at all, but *itself induces a plant to form definite*, and not indefinite, variations in nature; and, lastly, that definite variations are *always* in the direction of adaptation to the environment itself. The author then gives a concise epitome of the facts by which he hopes to make clear that the origin of species in plants is solely due to the direct action of the environment, and that Darwin, although fully recognising this principle, thought it to be exceptional, instead of its being the rule, in nature. The introductory chapter deals very fully with all the above-mentioned views, and contains a great deal of information bearing on the subject derived from many sources. The peculiarities of desert plants, alpine and arctic, maritime and saline, and phanerogamous aquatic plants are then successively and fully dealt with, and there are chapters on the origin of subterranean structures (roots and stems), peculiarities of climbing stems, and form and structure of leaves. With regard to the relations between roots and stems the author emphasises the fact that as a rule their differences are due to the direct results of the aerial and subterranean conditions of their normal existence, and experiments prove that when normally aerial stems are made to grow underground the new growth *at once* begins to assume the characters of normally subterranean stems such as rhizomes, and that both are in many ways comparable to roots. The conclusion therefore drawn is that it is the aërial and subterranean environments which act directly upon the responsive power of the organ, which then develops the structure appropriate for each medium respectively. Many interesting facts and theories are given about climbing plants, and the book altogether is most interesting and will be an addition to the International Scientific Series with which it is associated.

The Playground of Europe. By LESLIE STEPHEN. New edition. London: Longmans, Green, and Co. 1894. Price 6s.—The hazardous joys of Alpine climbing have seldom had a more competent exponent than the author of this entertaining work. In the vivacity and charm of his literary style he is excelled by few, and it is now more than thirty years since he made himself a name among the adventurous athletes who delight in scaling the mountain peaks of Switzerland and Savoy. "Excelsior" is the appropriate though quaintly expressed maxim of these enthusiasts. They have no mind to linger long in peaceful valleys or by the lake sides, but seek enjoyment rather in climbing precipices 1000 feet high or in tempting fate, tied three or four together to a rope, in situations inaccessible to a chamois. Such lovers of nature in her wilder aspects will not fail to relish the scene depicted in the frontispiece—an incident in the author's ascent of the Rothhorn in 1864, which he describes at page 110 as "the nastiest piece of climbing I had ever accomplished." It is not everyone who can attain either membership of the Alpine Club or Mr. Leslie Stephen's eminence in the higher departments of literary work; but to all admirers of perilous exploits among some of the grandest scenery in the world this record of his mountaineering achievements will be welcome.

Brain: a Journal of Neurology. London: Macmillan and Co. Summer and Autumn Numbers. 1895.—This last double number of *Brain* is one of very great interest. Amongst the original articles there is the address of Sir William Broadbent, as President of the Neurological Society, on the subject of "Brain Origin," while numerous papers of considerable scientific and clinical interest are contributed by Dr. Waller, Professor Wright, Dr. Michell Clarke, and others, together with an interesting discussion of the late Dr. Hack Tuke's important paper on Imperative Ideas. There is also a critical digest of recent psycho-physical literature and several reviews and abstracts. With such contents it is evident that this important publication at least keeps up its reputation. But we may suggest that it would conduce to the comfort and convenience of readers if the numbers were issued separately in their respective quarters, rather than that two should be issued together. The double number before us is a book of 287 pages.

NEW INFIRMARY AT SOUTHPORT.—On Thursday, the 26th ult., Southport began a series of celebrations which extended over the rest of the week by the public opening of the new infirmary. On the next day a marine drive and a bridge crossing the channel between the two marine lakes were dedicated to the public, and Saturday was given up to a brass band contest—a species of entertainment popular in Lancashire. In addition to the gift of five acres of land, valued at £5000, by the beneficiaries of the Scarisbrick Trustees, £25,800 have been sent on the infirmary. The building is of brick and stone and the front aspect is that of a quadrangle, with the men's wards on one side, the women's wards on the other, the administrative block in the centre, while behind are the children's ward, the laundry, and other buildings. There will be beds for sixty patients, and the nursing staff and servants will number about thirty. The extensive area round the hospital is laid out as pleasure grounds. The opening ceremony was performed by Alderman Dr. Wood, who is now mayor of Southport for the fourth time. He gave an interesting sketch of the growth from very small beginnings of the provision made for the sick in Southport. The Strangers' Charity was founded in 1806, and for fifteen or sixteen years the work was carried on in one or two hired rooms. "That," said Dr. Wood, "was the germ from which had sprung the convalescent hospital, the dispensary, and the infirmary."

A NEW FORM OF POCKET CASE.

MESSRS. MAW, SON, AND THOMPSON, of Aldersgate-street, have made for me a small "compactum" waistcoat pocket case, which I have kept in constant use for the last five or six years. It contains a clinical thermometer, which is thus saved from many dangers, a knife with Syme's and Paget's blades, scissors, a combination of probe director and grooved needle, dissecting or dressing forceps, and a caustic holder. There is, besides, a pouch at the back for needles, sutures, &c. This forms an armamentarium sufficient for the ordinary round of visits. The case lies flat, and without the slightest inconvenience, in the upper waistcoat pocket and takes the place of the weighty and inconvenient so-called pocket case. The dimensions are 4½ in. by 2⅝ in., the weight when filled is 2½ oz. and the price 30*s*.

Finsbury-circus, E.C. S. H. APPLEFORD.

THE CERES AUTOMATIC LETTER AND CARD FILES.

ALTHOUGH this system cannot, perhaps, be properly described as a *new* invention, having now been before the public some time, yet at any period one is always ready to welcome an improvement in the manner of conducting any of the varied and complex duties which combine to make up the day's work of the average business man, not the least formidable task in which is the (generally unsatisfactory) "putting away" of the large amount of correspondence &c. with which the majority of us are inflicted. To be in possession of the means to place one's hands almost instantaneously on a letter (or, for the matter of that, on anything that can be written, or printed, or pasted on a piece of paper or on a card) is a consummation many have at all times devoutly (or otherwise) wished for, but have dismissed as chimerical. Last January we expressed approval, at first sight, of the plan adopted by Mr. Bowater Vernon for keeping correspondence and papers in order by means of the Ceres Letter and Card Files. We have now tried the practical working of both the letter filing arrangement and the card system, and the result is that we can emphatically endorse all that has been said in their favour. For simplicity in use and ready adaptability to varying needs and requirements of work Mr. Vernon has devised a plan which will be difficult to rival. The plan of using cards or slips of paper is an outcome of the card catalogues now so familiar in our public libraries, with the important advantage of an automatically self-fixing support holding the cards or slips in position, and thereby dispensing with the troublesome and annoying necessity of threading them on, and unthreading them from, a rod, as is the case generally. The slip trays (which can be had for a few shillings each) should be welcomed by students and others for notes of reading or research, loose slips being much more handy than note-books for varying arrangement and classification. The new revised catalogue just to hand is more than an ordinary trade list, and it abounds in useful hints and suggestions for keeping letters, papers, &c., and for applying the card or loose sheet system to all manner of requirements. The files and cards can be seen at the offices of Messrs. Dawson and Sons, Bream's-buildings, Chancery-lane, W.C.

A NEW CATCH FOR FORCEPS.

I HAVE devised a catch, which Messrs. Mayer and Meltzer have made for me, for uterine and other forceps. From the figure it will be seen that the ordinary ring handle for the thumb is replaced by a catch curving down

THE LANCET.

LONDON: SATURDAY, OCTOBER 5, 1895.

IN the case of the researches of no man of the present century is it easier to gauge the enormous importance and the immense practical bearing that they have had than in that of LOUIS PASTEUR. The pertinacity with which he has adhered to the special detail at which he was for the time working, the faculty of demonstrating in the most clear but simple fashion such point, and the power of fitting these details when demonstrated into one harmonious whole to form a coign of vantage from which to attack other problems have always made PASTEUR'S work interesting, nay, even fascinating, to every educated mind; whilst the intensely practical character of many of his researches has gained the respect of those who can see good in no investigation on which £ *s. d.* is not written. PASTEUR, therefore, has received a meed of honour and reward even during his lifetime such as falls to the lot of few, even distinguished, men; but it may confidently be predicted that as his work is more fully appreciated, ridiculous as such a statement may seem at this time, and as its bearing on the study of the many still unsolved problems of disease is recognised, his reputation as an investigator will grow, and PASTEUR will stand out as an intellectual giant head and shoulders above his fellows. His early physical and chemical training developed in him an accuracy and a wealth of experimental resource without which little of his great work could ever have been accomplished; and his experiments on the tartrates and paratartrates, commenced when he was a young man, little as they seemed to bear on his after-work, really formed the basis on which most of his biological experiments rested. He was struck by the fact that during the process of fermentation of ordinary dextro-tartrate of ammonia in a solution containing organic matter a distinct micro-organism made its appearance. Then, too, he had been able to break up paratartaric acid by the addition of green mould, in the presence of inorganic crystalline salts such as phosphates and salts of ammonia only; this was accompanied by the disappearance of the dextro-tartaric acid and an increase in the number of fungi and bacteria in the fluid. Out of these experiments arose the controversy that raged round the subject of abiogenesis, and this was settled beyond dispute by experiments perfected by PASTEUR, although he followed the lines of those instituted by SPALLANZANI and SCHULZE, when he showed that bacteria and fungi, though developing most readily in those solutions which contained organic matter, were, nevertheless, capable of growing and multiplying in fluids in which no organic matter was present, so that the theory that they were developed from the running together of albuminoid molecules was once and for all time laid to rest. He further showed that fluids containing organised nitrogenous matter might remain unchanged for an indefinite length of time, even under conditions which, on the old theory of biogenesis, should be most favourable to the development of organised living cells, if care were taken to previously destroy any living organisms which might be already present and to prevent the entrance of such organisms from without. From this point the transition was comparatively easy to the position that fermentation and putrefactive changes, which only supervened when certain kinds of micro-organisms were allowed to gain access to fluids containing nutritive materials, were really the result of the action during their life-history of such micro-organisms. His researches on fermentation in connexion with French wines and his experiments with the mycoderma aceti soon convinced him that special kinds of fermentation were set up, given certain media, by different kinds of micro-organisms, each form having its own special fungus or bacterium.

The next step was the differentiation of a special etiological factor in the pathogeny of the silkworm disease, which at one time threatened to ruin the silk industry of France. He traced the "spot" disease or "pébrine" to the nosema bombycis, which had previously been described by NAEGELI as small, glistening, oval corpuscles which lead a parasitic life in the silkworm at its various stages; and by appropriate treatment—the destruction of all silkworm eggs that were suspected of being unhealthy—he was able to assist the silk-growers almost to stamp out this disease. He went beyond this, however, for he showed how certain chains of micrococci in the alimentary canal of the silkworm gave rise to another disease characterised by a peculiar lethargy. By these two sets of experiments he laid the foundation of the germ theory of disease, which has since borne such abundant fruit in the regions of practical and preventive medicine. He demonstrated the fact that certain specific organisms endowed with definite morphological and physiological characters are capable, by their presence and by the action of their products, of giving rise to specific infective disease; he pointed out the special *rôle* played by certain definite organisms in the production of different kinds of fermentation, putrefaction, and disease; and, in fact, on his observations and ingenious experiments as a basis built up a theory of a living contagium or rather brought it from a condition of chaos to a position protected from assault by a fortification of scientific proof. Instead of assigning to micro-organisms a general and common action in the initiation of the above processes he allotted to each one its own special part.

Such specific micro-organismal action having been traced in one or two instances, it was a comparatively shor step to the demonstration of an organised and living contagium in other specific infective diseases, and anthrax, fow cholera, and a number of similar diseases were in turn studied and with similar results. His next most important investigations were connected with the production of immunity by means of slight attacks of a disease set up by the use of a modified virus. His experiments on anthrax and fowl cholera may now be looked upon as classical, and there can be no doubt that, without his discovery of the action of specific organisms in the production of the several diseases with

Digitized by Google

which they are associated, the theory of toxines and antitoxins, which promises to play such an important part in the treatment of disease, could never have been advanced, or if advanced could never have been proved.

PASTEUR'S work in connexion with hydrophobia marked another great advance on any of his previous work, in so far as he was able to prove that not only could disease processes be prevented by "vaccination" prior to the injection of the *materies morbi*, but that the progress of the disease might be cut short or aborted even when the vaccination was carried on only after the virus had been introduced into the body. Much is written about the want of success in a certain proportion of the cases that have come under PASTEUR'S method of treatment for rabies; but anyone who will dispassionately and without bias examine the statistics of the results obtained in the various antirabic institutes, and compare these with the statistics of the cases that have not been so treated, cannot fail to be impressed by the enormous difference in the mortality under the two sets of conditions. Without vaccination the antitoxic serum method of treatment could never have existed, and it may be confidently anticipated that in all those diseases in which there is a localised formation of a poison, which in turn appears to act specially upon certain tissues, an antitoxic method of treatment may ultimately be obtained. It will, however, be a long time before it is fully recognised how great has been PASTEUR'S influence on this work, not only during the time that he was actively engaged in experiment, but also through the counsel and criticism which he bestowed on the work of his pupils and colleagues during the later years of his life. PASTEUR was always the head of the Pasteur Institute. Although he has not published a line since Dec. 27th, 1886—when he wrote his famous letter upon hydrophobia, which appeared in the first pages of the Annales de l'Institut Pasteur—his mind and hand may be traced, directly or indirectly, in every page of the nine volumes in which are recorded the work carried on in this Institute; moreover Listerism is the outcome of the application by a great surgeon to his own work of some of the principles which PASTEUR enunciated, as a result of which surgery has been raised from the level of a mere handicraft to the dignity of a science. PASTEUR was a man of a century. He had a great mind and an infinite capacity for detail; he had great tenacity of purpose, though his horizon was limited by no narrowness of vision. That he was a true Frenchman goes without saying, but his discoveries belong to the world. No man has contributed so greatly to our knowledge of the fundamental principles that govern the course of disease processes, and few have had so little to retract of what they have published. Such a result could only be the outcome of accurate working, clear thinking, and lucid exposition. It is interesting to note of such a man that his religion, his simplicity, and his affection for his parents and for his family were maintained unaltered in their purity through all changes and controversies. His was not the wisdom of the agnostic, but the faith of a clear-sighted man who, interpreting much through his grand intellect, was still conscious of a world beyond that which he had probed deeper, perhaps, than any of his fellows. France may well mourn the loss of such a man; and all men, irrespectively of nationality, who have a love for truth and an admiration of directness of purpose and keenness of intellect must mourn with her.

ONE of the greatest triumphs which medicine has achieved during the last few years is in the successful employment of the natural secretions of the animal body in the treatment of disease. Such therapeutic methods are the more to be valued since they are founded on a rational rather than an empirical basis. Nothing can be more satisfactory to a scientific physician than to control a disease by supplying to the body a substance the deficiency of which has caused the morbid process in question. The greatest success in this line of treatment has been in cases of myxœdema. This disease was first described as cretinism in adult women by Sir WILLIAM GULL, and the name which it now bears was given to it by Dr. ORD on account of the excess of mucin in the skin, which he found in several cases. Further experiments on monkeys by Professor KOCHER and others abroad and by Mr. VICTOR HORSLEY in England showed that all the symptoms of myxœdema were produced by removal or atrophy of the thyroid gland, and attempts were thereupon made to counteract these symptoms by the grafting of healthy thyroid on to that which had been removed or atrophied. As might have been expected, the practical difficulties attendant on this operation were found to be insuperable, but the principle was established, and from that time forward the methods of artificially supplying the organism with the products elaborated in the thyroid gland passed through rapid stages of simplification till they reached the compressed forms which are now so familiar to everyone. The success met with in cases of myxœdema prompted an investigation into the action of thyroid juice on other diseases, and the condition known as exophthalmic goitre, or Graves' disease, was naturally among the first of those to which attention was directed. This disease and myxœdema are in some respects the antithesis of each other. The enlarged thyroid gland of Graves' disease is one of its most conspicuous features, while the almost invariable tendency of such patients to have the emotional part of their nature unduly developed contrasts remarkably with the mental dulness and apathy of myxœdema. Over-secretion of the thyroid gland, therefore, at once suggested itself as the starting-point of Graves' disease, but this plausible theory has not yet received any decided clinical verification, although some cases have been relieved by the extirpation of the gland. It is possible that in the enlargement of the gland the secretion may undergo some subtle chemical change which, though its nature is at present unknown, may ultimately be counteracted by some simple means. Thyroid feeding in myxœdema has long since passed beyond the stage of experiment and inference, and has come to be recognised as a remedy of unquestionable efficacy. It has been used experimentally in many other diseases, and has met with some considerable success in certain affections of the skin, but here we are unable to follow the therapeutical methods by which a cure is effected, and, moreover, it is doubtful if its action is sufficiently reliable. The direct relation of the thyroid gland to myxœdema and its undoubted therapeutic efficacy

Digitized by Google

when administered in cases of that disease opened up the way to the investigation of the action of the other so-called ductless glands, and an extensive knowledge of their actions is being obtained. Professor SCHAFER in his Address in Physiology at the recent meeting of the British Medical Association gave a full account of our present knowledge of this subject, much of it being the result of his own indefatigable work. To all appearance the use of "internal secretions" has a great future before it in the treatment of disease. The extension of our therapeutic resources due to this discovery, together with the introduction of antitoxic serum, mark an important stage in the advance of medicine as a healing art.

THE First of October, as Sir JAMES PAGET said, is a New Year's Day to the medical student, and, if he takes careful note of the counsel of his wisest advisers as given to him in the opening lectures and in other ways, he may make the day to be "the fair beginning of a time." In the introductory addresses there is a variety which may satisfy all tastes. Possibly there are one or two that will confirm the cynics in our profession in their disrespect for such occasions. In these the speakers seem to flounder about from one thing they have heard to another, without point, without connexion, and without dignity. But these are the exceptions, and the first-year student, or the fifth-year student for that matter, must be "wise in his own conceit" who can scan the introductories of the year without feeling that they abound in inspiration and in instruction which will serve them in quiet moments of duty, of temptation, and of difficulty. We should be prepared to judge students and to forecast their future success very much by their reception of such truths as find expression at the opening of sessions. Much has been said of late as to the need for more explicit ethical teaching in our medical schools. It exists already, and is most pronounced on the opening days of the session, when the many-sided relations of the profession are demonstrated, and the claims of the public, of patients, of the poor, of the lower animals, and of fellow practitioners are all insisted on; when all mean devices for getting practice are denounced, and when all careless and slipshod work, all defect of sympathy, and all "doing" that falls short of what Sir JAMES PAGET called "doing one's best" is pronounced to be unworthy of the profession to the practice of which the new students and the old students alike aspire.

It is difficult to single out individual addresses for special notice. Each mind, according to its bent, will make its own selection, and what will strike one as interesting will appear to another to be either forced or commonplace. We shall endeavour rather to emphasise subjects than individuals in what little we have to say. We may make one exception in the case of Sir EDWIN ARNOLD. When a distinguished layman, representative of literature in its widest and highest forms and in its most useful and varied applications, does the profession the honour of undertaking the opening of a great medical school and gives us his views of the profession to which he does *not* belong, when he magnifies every virtue of the profession and summons all his powers of euphemism not to suggest any possible thought of fault in its methods, it is both just and pleasant to give much heed to what he says. He gives us the great advantage of "seeing ourselves as others see us." In this aspect all will study with rare interest the picture drawn by Sir EDWIN ARNOLD of what is, in his judgment, "the best, the gentlest, the loftiest, and the purest of the secular crafts which men follow." If this be a true judgment of our craft, what more of ethic is needed by the student who enters on it than the call to prepare for it, to live up to it, and to watch day by day the men who best exemplify it? The old satirists of medicine have had their chance and they have used it. But they would find little in medicine now on which to feed their "immortal scorn," and our present danger is lest we be too much elated with the tribute of outsiders who see the drift of the great movements which have revolutionised medicine, and who are too generous and too much outside the profession to see its remaining faults. He will be a dull student who can read this great panegyric of our art without emotion and without the desire to distinguish himself by advancing the growth of some branch of "the great tree which is set for the healing of the nations," whether it be in the slums of our own European cities or in the Zenanas of the East, which Sir EDWIN ARNOLD so vividly presents to us as spheres for medical women. We cannot forbear one allusion to his plea for consideration for the lower animals in the matter of vivisection. Our own views on this subject have never varied, and they do not differ from his. We should be ready to exclude from the profession the man who wantonly and in the name of medical science inflicted unnecessary cruelty on the meanest animal. While recognising that man is "of more value than many sparrows," or even many dogs and many horses, we recognise the solidarity of all living things and the obligation of the greater to the less; and we feel sure that the profession will join with us in thanking Sir EDWIN ARNOLD for his exquisite gentleness in dealing with this great theme, and his generous recognition of the humanity of those who exist to diminish suffering and to prolong life. The relations of pharmacists and medical practitioners were handled admirably and courageously by Dr. FREDERICK ROBERTS in his address to the Pharmaceutical Society. At Owens College Dr. LEECH vindicated the ethics and methods of HIPPOCRATES as good for all time and at the root of all good conduct and practice. HIPPOCRATES is, after all, the Father of Medicine, and we may well be content to forget some of our "forefathers" in favour of him. Another great function of our profession was the theme of attention at St. Mary's Hospital in the address of Dr. A. P. LAURIE, whose public duties have led him to consider the bearing of various industries on the health of the people. Some of these, if not checked, threaten racial degeneration. The insidious dangers of lead and phosphorus and other poisons, of breathing an atmosphere of dust, and of working at high temperatures still confront those who have to protect the health of British workmen, and in regard to these subjects Home Secretaries must be guided by medical men. Dr. LAURIE suggests that far higher duties and far higher pay must be forthcoming

Digitized by Google

for surgeons under the Factory Acts than any yet contemplated.

We have come to the end of our space. But we have said enough, we trust, to lead our readers to study the addresses and to realise for themselves their responsibilities as students and practitioners of an art of which so much is expected and to which such great honours are already paid.

Annotations.

"Ne quid nimis."

PRESENTATION TO DR. HUGHLINGS JACKSON.

THE opening day of the medical session of 1895 will be memorable in the history of the London Hospital Medical School. The occasion was made one of exceptional interest by the presentation of his portrait to Dr. Hughlings Jackson, together with a silver ewer and stand. The presentation was subscribed for by Dr. Jackson's medical and surgical colleagues on the staff of the London Hospital and numerous friends both at home and abroad, "in recognition of their esteem and admiration of his great services to the London Hospital and Medical College, his distinguished position in the profession, and the advances he has effected in medical science by his laborious investigation and profound insight into diseases of the nervous system." Another portrait by the same artist was presented to the medical school of the hospital. Dr. Hughlings Jackson is one of the least demonstrative members of the profession, but this quality only increases the singular interest and, we may add, the affection with which he is regarded, not only by his colleagues, but by the profession in every part of the United Kingdom and of the world. The authorities of the Medical School were fortunate in getting Sir James Paget to preside and to make the presentation. The catholic nature of the occasion was shown by the presence of Professor Burdon Sanderson, Sir Spencer Wells, Sir William Broadbent, Dr. Barlow, Dr. Buzzard, and others. Sir James Paget spoke, as almost only he could speak, in regard to the professional history of Dr. Hughlings Jackson and the character and significance of his work. It was his rare satisfaction to be able to revert to the fact that among the generations of students whom he had taught were the names of Dr. Hughlings Jackson and Mr. Jonathan Hutchinson, the latter of whom was unfortunately and unavoidably absent. He dwelt on the constant effort of Dr. Hughlings Jackson to bring all clinical facts and all scientific ones into harmony for the practical good of the patient, and touched with special emphasis on his fruitful researches into the localisation of brain function, which had given lucidity to physiology and guidance to surgery. Dr. Hughlings Jackson's reply was characteristic in the extreme and was of much scientific and biographical interest. He said that some of his most important observations were made in the out-patient department. He was careful to say how much the pleasure of the occasion was enhanced to him by the presence of Sir James Paget and the numerous friends by whom he was surrounded. His colleagues, through Dr. Stephen Mackenzie and others, gave very eloquent expression to the sentiments with which Dr. Hughlings Jackson was regarded by them and to the hope that for years yet to come they would be able to have his opinion and his help as consulting physician to the hospital. It is worth recording that Mr. Hutchinson once told Dr. Mackenzie that the greatest work he had ever done was to discover Dr. Hughlings Jackson. The proceedings were made still more interesting by the presentation of prizes to the successful students by Sir James Paget, and to the nurses of the hospital by Mrs. Hale, the wife of the chairman of the hospital. In this part of his duties Sir James Paget gave very explicit expression to his opinion that the existence of a medical school in connexion with a hospital is a great advantage to the work of the hospital—a great security for better clinical work and better care of the patients. No Government inspection could be so good as the daily criticism of observant and intelligent students. Taken altogether, the school of the London Hospital may be congratulated on the opening day of the session in its happy combination of a well-earned tribute to a leader in medicine of whom we are all proud, and in its encouragement to students, who will not soon forget either their prizes or the words of dignified wisdom with which they were presented. The lay authorities of the hospital were represented by the chairman (Mr. John Hampton Hale) and the treasurer (Mr. J. H. Buxton).

PRECEPTS FOR CYCLISTS.

CYCLING seems to be quite as popular in France as it is with us, and yet there are medical authorities amongst our neighbours who condemn the practice because, in their opinion, it is liable to be attended by cardiac or circulatory troubles. It is true that in this country similar allegations have been made; but, so far as we are aware, the charge has never been seriously maintained, and no well-authenticated cases of disease arising from the use of the cycle have been placed on record. On the whole, it may safely be said that self-propulsion on two or three wheels is about as salutary a form of out-door exercise as could well be devised, provided always that the injurious and hideous bent posture affected by "scorchers" be rigorously condemned and avoided. It must not, however, be inferred from this ability on the part of the Anglo-Saxon race to indulge in cycling, with not only impunity but benefit, that the rule is likewise applicable to the members of other nationalities. All English schoolboys are accustomed to out-door sports of a more or less violent character from their earliest youth—cricket, football, tennis, and other athletic games of various kinds are as much part and parcel of the curriculum in our schools nowadays as the Latin grammar, if not more so; and thus it comes to pass that very few adults arrive at maturity with their organs and muscles uninured to intermittent extra calls, in every shape and form, upon their powers of endurance. Our rising generation enters upon life physically prepared for any emergency, and thanks to this early training it is that cycling may be regarded as practically harmless, even though its votaries should postpone their initiation until comparatively late in life. Now, although in Great Britain there may be no medical objections to cycling when judiciously carried out, there are certain attendant circumstances involved in the practice abroad which demand consideration. Generally speaking, it may be said that in the matter of physical exercise the system of education usually adopted on the Continent is totally different from ours. Sports and pastimes are but little encouraged in foreign *lycées*, and such as do exist are for the most part sedentary performances scarcely deserving to be classed as trials of strength and stamina. The youths consequently grow up unfitted to withstand the severe strain of cycling, and the circulatory apparatus is naturally the first portion of their economy to give way under the unwonted exertion. The foregoing remarks were suggested by some "precepts for cyclists" that have been drawn up by M. Rocheblanc for the benefit of his fellow countrymen. It is not likely that, so far as the male sex is concerned, the recommendations will be adopted on this side of the Channel, but their reproduction may be advantageous to the

Digitized by Google

ladies who have taken up cycling with such marvellous energy. Girls do not serve the same apprenticeship to rough games that boys do, and therefore the French physician's warnings are more pertinent to their case. 1. No one should become an habitual cyclist without medical authorisation. Before committing himself to an opinion the medical man consulted will do well to examine the beginner on dismounting from the machine as well as beforehand; there are certain cardiac defects which only become recognisable when the subject is under the influence of excitement or fatigue. 2. A cyclist should at first be content with a moderate pace, not exceeding twelve kilometres per hour (about seven miles and a half). A higher rate of speed should only be indulged in after the rider has gone through a regular course of training. If a break in the practice occurs, lasting even a few days, the cyclist should recommence at the slower rate. 3. The temptation to go quickly must be controlled as far as possible. A bicycle travels well-nigh of its own accord, and it is very hard to resist the "delirium of speed." With a light machine on a good road, and helped ever so little by the breeze, an amateur, even when only half trained, can easily achieve his twenty-five kilometres within the hour (fifteen miles and a half). This is too much, seeing that when doing from fourteen to sixteen kilometres the rider's pulse rises to 150.

WEATHER AND HEALTH.

FOR once the lacking arrears of an uncertain summer have been paid in full measure and with almost unbroken regularity. Now there are signs of a change, though whether this will endure in its present phase or will itself give place to another season of late but continuous warmth it is impossible to predict. The past month has not, on the whole, been an unhealthy one as regards the more usual causes of dangerous illness. Diarrhœa alone of the series occupies a pre-eminent position, and it has been by far the most frequent cause of mortality. This circumstance is not in itself remarkable, since we are accustomed to regard the months of early autumn as peculiarly liable to the prevalence of this disorder. The recent season of unusual heat has added a fresh testimony to the truth of this observation. It has also shown that, as in former years, excessive solar temperature only tends to emphasise that testimony. There are obvious reasons which account for this effect. The more rapid evaporation of subsoil water with its contained impurities, the increased rapidity of putrefaction in many articles of diet and in decaying waste matter, whether animal or vegetable, and the like processes in drains and in badly ventilated living rooms have each their share in the work of causation. Accordingly, there is no occasion for surprise that the recent sultry month has been marked by a much more than ordinary prevalence of enteric disorders. A rise in the mortality from diphtheria is accounted for on the same grounds. Summer heat brings with it another danger, and this, too, has been somewhat more than usually active during the past fortnight—namely, the liability to chill. We are all familiar with dilemmas as to the amount of clothing suitable to a climate which is out of season, and therefore daily liable to variation. We have all felt the inconvenience of exertion in such weather as that of last September, and some have doubtless also realised the treacherous after-chill which readily follows the slightest exposure while overheated. There should, therefore, be no difficulty in accounting for an increased mortality from diseases of the respiratory organs during our autumnal summer. With the beginning of another month comes a change of weather, a cooler and in so far a truer season, although attended with damp morning mists. Somewhat sudden in its arrival, it may, if not watched and provided against, surprise some who are still uncertain whether to break definitely with the genial warmth which is still so recent. Such persons, especially if not young, will, if wise, incline to the side of caution. The airy liberty of widely opened doors and windows, the remembered comfort of light clothing, and the quiet and freedom of cool evening rambles are no longer to be reckoned among guaranteed methods of recreation. September established a record of exceptional warmth. October, though not yet to be described perhaps as "chill," rather suggests a belief that it will before long exhibit its usual characteristics.

DEATHS UNDER CHLOROFORM.

WE are indebted to Mr. E. V. R. Fooks, the acting medical superintendent of the St. Saviour's Union Infirmary, East Dulwich, for the particulars of the following case. The patient, a girl aged fourteen years, was admitted into the infirmary on June 5th suffering from tuberculous glands in her neck. The glands had suppurated and formed an abscess, leaving an intractable sinus. On Sept. 11th it was decided to scrape the sinus. Chloroform was given, being dropped upon lint in small quantities. Before administration the patient was examined and pronounced to be free from organic disease. The anæsthetic was commenced at 11.35 A.M., and within a few minutes, when two drachms had been given, struggling took place, and some cyanosis soon appeared about the lips. The chloroform was withdrawn at once. The respirations were, it is stated, still going on, but the pulse weakened and became imperceptible. The pupils reacted to light up to the time that cyanosis appeared; they then became widely dilated. Strychnine was hypodermically injected, inversion (Nélaton's method) was practised, and as soon as natural breathing ceased artificial respiration was commenced and continued for one hour and twenty minutes. "The battery was applied over the vagus and præcordial region." The operation was not commenced. Death took place twenty-five minutes from the time the chloroform was first given. At the necropsy it was found that there was dilatation of the right ventricle by fluid blood and some congestion of the cerebral vessels was noticed. The chloroform was administered by the medical superintendent. Death would appear to have been caused by an overdose being inhaled during the stage of struggling, and was probably caused by respiratory rather than by cardiac failure, although respiratory movements are noticed as having occurred even after the pulse had failed. There was evidently some obstruction to the passage of the venous blood through the lungs, and this would rapidly bring about cardiac failure. Whether electrical stimulation over the vagus and præcordium is likely to help the heart's action in these cases is at present open to doubt. The inhibition of the heart has been held by some authorities to be protective by lessening the flow of chloroform-laden blood to the nerve centres. This, however, must be an undesirable thing in one cyanosed by chloroform. Certainly stimulation of the vagus would be likely to produce this cardiac inhibition. Stimulation of the phrenics is of less questionable value whenever it is possible to limit the spread of the current and protect the vagus from this overflow current. Other deaths under chloroform have recently occurred. In one the patient was a female infant aged fourteen months who was taken to the London Hospital. The child was found on admission to be in a very grave condition. There was an enormous swelling under the jaw on the right side of the neck, which affected the breathing. Fluctuation was felt, and the tumour was diagnosed as a case of tuberculous glands which had suppurated. The infant took a "few whiffs" of chloroform, and the abscess was punctured. On the completion of the little operation the

Digitized by Google

child was placed in bed and died very soon afterwards. The surgeon in charge informs us that the death was not due to shock from the operation, although possibly in the weak state in which the infant was the shock may have accelerated the fatal result. Probably the same may be said of the chloroform. The case is clearly one of death *under* chloroform rather than *from* chloroform. A very similar case is reported from University College Hospital. A girl aged seventeen months was admitted on Sept. 18th suffering from a large abscess in the right lumbar region. Although fairly developed she was pale, and had bronchitis and a temperature of 100·4° F. On Sept. 20th the abscess—perinephritic in nature—was opened. Chloroform was given by a house physician from lint, some three drachms being used in about ten minutes. As soon as the child was fairly under the abscess was incised and much pus evacuated. Simultaneously the respiration stopped, but the pulse was perceptible for some minutes afterwards. There was some difficulty at first in getting air to enter the chest, so a tube was passed down the trachea. The usual measures for resuscitation were adopted. The necropsy showed all the organs to be pale; no venous engorgement was seen. This again seems to be a death due to operative measures reacting on a weakly patient. A verdict of "Death by Misadventure" was returned by a coroner's jury at Newport, Monmouthshire, last week, at an inquest held on a patient who had died in the Newport Infirmary. The deceased had recently received an injury to his finger, which necessitated the amputation of a portion of it. A few days later it was requisite to perform another operation higher up. Chloroform was administered in the presence of four members of the profession, but shortly after the anæsthetic was commenced the respiration ceased and the patient died before the operation was attempted.

ALCOHOL IN IRISH WORKHOUSES.

WE are indebted to the Irish Association for the Prevention of Intemperance for a return of the amounts of alcoholic beverages consumed in the various workhouses in Ireland during 1891 and 1893. The return shows a total decrease in the expenditure on spirits, wine, and malt liquors during the latter period of 3*d*. per head of the inmates. When we come to an analysis, however, the progress of retrenchment is not so clearly seen. Out of 159 unions three are consistently abstinent and spend nothing on alcohol, seventy-three have a diminished liquor bill, while in eighty-three the consumption has increased. The sums expended in different cases vary in the most eccentric manner from 1*d*., 3*d*., or 6*d*. to 15*s*. 7*d*. per head. It is remarkable, also, that the highest figures have been reached by the smaller establishments, the palm for expensiveness being borne by Carrickmacross with 124 inmates, while Belfast with 3106 pays but 3*s*. 10*d*. per head for alcohol. Cork, North and South Dublin, and Limerick, which also provide for many poor, tell the same frugal story. On the other hand, some of the smallest unions are the most economical: Stranorlar, which has 66 occupants, is totally abstinent; and Westport has 168, and spends 1*d*. on each. A somewhat larger institution, that of Newry, houses 213 persons, and allows nothing for alcoholic liquors. Thus, if opinions respecting the necessity of supplying stimulants to Irish workhouses do not quite correspond in number to their official guardians, they do traverse a long and costly scale between the emphatic *nay* and the equally positive *yea*. In discussing this question we are by no means disposed to accept without reserve the authority of mere statistics. Some latitude must in reason be allowed for explanation, and it may be that necessities of illness have had something to do with the origin of otherwise remarkable differences of expenditure quoted in the report under consideration. Alcohol as a drug has its legitimate place in medical treatment, and this fact is not affected by the social standing of those who require it. To admit this, however, implies no sanction of its routine or general use. Weakness, illness, or old age may each constitute an occasion for its employment, but only under the prudent supervision of medical authority. It would be interesting to learn whether this authority has been invariably consulted in providing stimulants for the use of inmates in Irish workhouses, and, if so, whether its influence has been exerted in each instance with due vigilance and exactitude. If the requirements of weak and sick persons are sufficient to explain the increased outlay on alcohol where this has been incurred, we have nothing further to say; but we fail to see that the ratepayer need go beyond this point in the exercise of his parochial duty. The report before us will have done good service if it leads to such an inquiry as will furnish an explanation of the costly discrepancies in expenditure to which it directs attention. Such an investigation would certainly seem to be called for in the public interest.

UNUSUAL PROCEDURE AT AN INQUEST.

AT an inquest on Sept. 24th, 1895, held by Dr. Eugene Yarrow, deputy-coroner for North-East London, the jury, seventeen in number, could not agree, twelve being in favour of a verdict of accidental death, and five, including the foreman, being of opinion that there was negligence. The coroner decided to take the finding of the twelve. The question has been raised whether the verdict was not illegally received, inasmuch as the foreman's signature was not attached. From the fact that the foreman has the oath administered to him primarily and separately, it seems reasonable to infer that the Legislature intended the verdict of his fellow jurors to be delivered through him. At the same time the jury need not consist of more than twelve, and consequently it is arguable that if that number return the same finding the section of the statute is satisfied. Considering the uncertainty attaching to the intentions of the Act, it would be well if a case were stated for the opinion of a superior court. Should the proceedings be declared null and void a fresh jury would have to be empanelled, and as the inquest has to be taken *super visum corporis*, exhumation would be necessary, a circumstance at once objectionable and vexatious.

THE DISPENSING OF PHYSICIANS' PRESCRIPTIONS.

ACCURACY in dispensing is obviously one of the most important factors connected with the treatment of disease; but although this is so it must, we fear, be admitted that the quantitative analysis of medicines made up from physicians' prescriptions is not as yet carried out on a scale in any degree proportionate to the importance of the subject. It is for this reason more particularly that we welcome a report of Dr. Bernard Dyer, the county analyst of Leicestershire, which he has recently made to that county council upon the quantitative analysis of thirty-nine samples of medicine obtained by submitting to druggists in the county prescriptions for a tonic containing iron and quinine. Dr. Dyer reports with pleasure that of the thirty-nine samples analysed thirty-six were both accurately dispensed and properly labeled. In regard to the remaining three samples, it appeared that in one the mixture, although dispensed in accordance with the prescription, was inaccurately labeled and the patient was directed to take two teaspoonfuls for a dose instead of two tablespoonfuls, as ordered; in the second case the mixture was slightly too strong; and in the third the amount of quinine was two and a half times in excess of that prescribed. In none of these cases does there seem to have been any attempt to defraud the public in the sense of depriving the patient of the full

Digitized by Google

benefit anticipated by the prescription; but unfortunately, in the matter of some drugs, though not in the case of those specifically referred to here, sins of commission might have been far more disastrous than sins of omission, and an increase of strength to the extent of two and a half times that ordered might lead to a fatal result. In the making up of prescriptions absolute accuracy alone is allowable. We trust that Dr. Dyer will continue his investigations in this direction, and we would suggest the desirability of paying attention to pills, powders, capsules, &c., which would seem from careless mixing to be peculiarly liable to quantitative variations. In cases where undue parsimony in the execution of prescriptions is suspected it is to the more expensive drugs that attention should be directed, whereas in the matter of carelessness the nature of the drug is obviously immaterial.

THE FIFTH YEAR'S CURRICULUM.

WE are glad to learn that some of the special hospitals are altering their arrangements in order to meet the needs of the fifth year's curriculum. At the Brompton Hospital the facilities for the study of diseases of the chest are to be increased by the formation of two new appointments. Clinical clerks are to be allotted to each in-patient physician and clinical assistants to the out-patient physicians. In addition, all students who enter (at a small fee) for the practice of the hospital will be enabled to make use of the vast amount of material (whether clinical, pathological, or bacteriological) that such a hospital affords. A course of lectures on the principal diseases of the thoracic organs is to be delivered each session, open to students of the hospital and to all qualified medical practitioners on presentation of their cards. The opening lecture will be given by Dr. Douglas Powell on Wednesday, Oct. 9th, at 4 P.M., on Angina Pectoris. Full information can be obtained either from the secretary of the hospital or from the deans of the medical schools of the metropolitan hospitals.

THE INCREASING PREVALENCE OF RABIES.

FOR some time rabies has been on the increase in the United Kingdom, and more especially in Ireland and England. In the northern and midland counties, particularly Cheshire and Lancashire, it is never absent, and reports of deaths from hydrophobia due to the bites of rabid dogs are frequent in these regions. But, as on many previous occasions, the malady has been extending southwards in England; and, as has been predicted over and over again for the last quarter of a century, the prevalence of the scourge in the midlands always leads to an extension in other directions, chiefly towards the south. In the London district an increase in the number of cases of rabies has been noted for some time, and precautionary measures must soon be adopted if a serious outbreak of the disease is to be averted. In Surrey the county council has issued a dog-muzzling order, and if this is energetically carried into operation it is possible that the lives of people and animals may thereby be saved. At any rate, a cause of dread to the inhabitants of the county may be obviated by this procedure. But, as usual when muzzling of dogs has to be resorted to for the prevention and suppression of rabies, there is an outcry against the measure, generally from those who know nothing of the nature of the disease or of the measures required to deal with it. In a Surrey newspaper, for instance, there is a letter declaiming against the employment of this measure, and showing a great amount of ignorance of everything pertaining to the subject—ignorance which is unpardonable, considering the amount of information everywhere accessible, when it is remembered that the writer is opposing a measure which is intended to protect human beings and animals from a most agonising death, and that he ignores the experience gained through many years' use of the muzzle, not only in this country, but in France, Germany, Austria, Belgium, Denmark, and elsewhere. The writer does not believe in the existence of rabies, and confesses himself more ready to give credence to the appearance of ghosts than of mad dogs; though on this point his credulity leads him into a contradiction, as he confesses that dogs may become rabid by the use of the muzzle, but says that if they are treated as they should be they will not do so. The writer would seem to be one of those individuals who, destitute of knowledge of contagious diseases, are moved through pseudo-sentimentality to oppose any steps for the alleviation or eradication of one of the most terrible diseases that can afflict man or beast, and who are not ashamed to air their ignorance in the public press or on the anti-hygienic platform. Surely at the present day educated men ought to know that rabies cannot be produced by muzzling or anything else, save by the bite of a rabid animal or by the introduction of its virus into the blood of a healthy one. It is a specific disease, and can only be imparted by a diseased creature which has received the infection from one already infected. The nonsensical objections to the muzzle come from people who are unaware of the evidence upon which its utility is based, and of the opinions of men who have made a special study of the disorder. The muzzle, if properly constructed and fitted, is no more annoying to dogs than is the bit in the mouth of the horse. The compulsory wearing of muzzles is a measure calculated to benefit the canine species as much as other animals, or man himself, and facts testify that whenever and wherever this measure has been adopted the disease has soon disappeared. It is the unmuzzled wandering dog that disseminates the disease. The only objection to muzzling should be that it is not made universal during the prevalence of rabies.

SHOULD THE HEART BE EXAMINED BEFORE CHLOROFORM IS GIVEN TO A PATIENT?

THIS important question was debated at some length between the coroner and some medical men at a recent inquest. A patient aged forty years was admitted into the infirmary to undergo an operation for cancer of the penis. Upon admission he was examined by the assistant house surgeon, who pronounced his heart and lungs to be normal. The man was very nervous about the anæsthetic and expressed himself as being so. He placed himself on the operating table, and chloroform was given "in the usual way," by which we presume the Scotch or open method is meant. The patient took it well at first, but shortly a surgeon who was standing by felt the pulse and remarked that it was extremely feeble. We may presume that the respirations were up to this point not affected; they are said to have become short after this. The patient was at this time beginning to go under, but was not fully anæsthetised. Restoratives were tried, but no rally occurred. In answer to the coroner and a juryman, the chloroformist admitted that he had not examined the heart and deemed so doing quite unnecessary. "The worse the heart the greater the need of chloroform." The man was said to die from shock, but it was added, "I do not suppose he would have died from shock had chloroform not been administered"; and further we are told that "every day they were giving chloroform to people with all sorts of heart disease. That it was wrong to do so was an exploded idea with the profession, although it remained to some extent with the general public." These statements are too sweeping to be passed by without comment. That each medical man has a right to his opinion all will readily admit; but no one is justified in saddling the profession at large with his views or even those of his school. Upon the question of examining a

Digitized by Google

patient before taking an anæsthetic, it is clearly the duty of the person with whom the responsibility of the case rests to satisfy himself as to his patient's general fitness, and to select with the utmost care the anæsthetic which will be best for the particular case. It is also advisable that this should be done any day before the operation rather than immediately before the administration, provided always that the patient has been sufficiently under observation for the chloroformist to be sure that no acute intercurrent illness has appeared in the interval between the examination and the administration. This wise course seems to have been adopted in the present case. When, however, we weigh the other points in the evidence we do not find ourselves in accord with those who gave it. That "a weak heart needs an anæsthetic" we allow, but we can neither admit nor believe for one moment that the profession considers that "the worse the heart the greater the need of chloroform." Undoubtedly the clinical experience of the past thirty years or more has shown that deaths from heart failure or "shock" of the kind described in the report before us are most rare under ether, if they ever occur, where it is properly given; while under chloroform they are unfortunately by no means uncommon. We do not for one moment suppose that the greatest care and acumen were not shown in the case under discussion, nor do we doubt that there were good reasons for selecting chloroform for the operation; but we cannot but take exception to the statements reported to have been made, not on the authority of one surgeon, however eminent, but as *ex cathedrâ* and representing the opinions of the medical profession at large.

COUNTY COUNCILS AND LOCAL SANITARY AUTHORITIES.

AN inquiry of considerable interest from the point of view of sanitary administration was held recently by Dr. Sweeting at Auckland Workhouse on the part of the Local Government Board. The Durham county council had apparently complained to the Board that the rural district council of Auckland was not, in certain specified parishes, doing its duty in the matter of scavenging, and the question arose as to whether the district council should not be compelled to carry out its obligations in this respect. There was a large attendance of interested persons at the inquiry, and Dr. Eustace Hill, the county medical officer of health, took a prominent part in the proceedings, producing much evidence in support of the county council's contention. The accusation was, however, denied by the district council, whose representative argued that the action of the council had been "hasty and uncalled for," and that the service of many notices was in itself evidence of activity. Dr. Hill, however, rightly observed that activity by no means implied efficiency, and that the enforcement of the notices was the essential point. As, too, the county council had waited for three years before lodging the complaint it could hardly be accused of precipitate action. The evidence of the district council's medical officers of health seems to have been on the whole decidedly favourable to the county council's position, but numerous parish councils in the district opposed the application that the duty of scavenging should be imposed upon the district council. There seems, however, to have been an almost universal consensus of opinion that the condition as regards West Auckland was very bad. The district councillors contended that the council had but recently been formed, and that time had not yet been afforded them of putting their house in order; it was obvious, too, it was urged, that those who lived in the villages complained of were better judges of the necessity of reform or alteration than periodical visitors, &c. With these arguments we are not altogether unfamiliar. The prospective formation of district councils was the excuse for delay and neglect on the part of the old local bodies, and the recent election of the district councils will be made to serve a somewhat similar purpose for months to come. When, however, it is remembered that in many instances the personal constitution of the two bodies differs but slightly, the argument loses some of its force. Doubtless this matter will be well sifted by the Medical Department of the Local Government Board, and the evidence which has been adduced will, we imagine, render the scavenging, at least in the worst villages, compulsory on the district council.

LONDON POST-GRADUATE COURSE.

THE first lecture of the winter term will be given on Monday next, Oct. 7th. The following hospitals and institutions have arranged a scheme of work:—The Hospital for Sick Children, Great Ormond-street (Children's Diseases); the National Hospital for the Paralysed and Epileptic, Queen-square, Bloomsbury (Nervous Diseases); the Royal London Ophthalmic Hospital, Blomfield-street, Moorfields (Diseases of the Eye); Bethlem Royal Hospital for Lunatics (Diseases of the Mind); London Throat Hospital (Diseases of the Nose, Ear, and Throat); Bacteriological Laboratory, King's College (Bacteriology); and the Central London Sick Asylum, Cleveland-street (General Medicine and Surgery). Practitioners can suit their own convenience as to the number of courses they take. The diary is so arranged that none of the hours for lectures clash one with the other, and time is allowed for hospital practice. All information can be obtained from Dr. Fletcher Little, the Secretary, 32, Harley-street, W.

THE EAST LONDON WATER INQUIRY.

THE proceedings of the Local Government Board inquiry into the alleged inadequacy of the water-supply of the East London Company during the recent summer months were commenced at the Hackney town-hall on Tuesday last, the Local Government Board being represented by the departmental inspectors Colonel W. M. Ducat, R.E., and Dr. F. W. Barry. Public interest in the subject appears to have flagged somewhat since the time when meetings were held at which resolutions were passed calling upon the Local Government Board to investigate the matter, for the proceedings closed at an early hour owing to the non-attendance of witnesses. The evidence, however, so far taken, has been chiefly given by medical officers of health whose duties are in the districts involved and by residents in Hackney. Mr. Balfour Browne opened the case for the local authorities by defining the scope and character of the inquiry, and by explaining that it was taken under the Water Acts and the Public Health (London) Act at the instance of delegates from the vestries affected. There was no doubt, he said, of the scarcity of the supply, and he would call witnesses to prove its extent. They would then await with interest the company's explanation. Already, however, the company had attributed their neglect to provide additional storage reservoirs to the opposition of the county council, who rejoined that their opposition was directed against other provisions, and that if new storage reservoirs were required the company might have provided them without any Bill by sacrificing some of its large profits. Several medical witnesses then proceeded to describe the great privation they had suffered and the prejudicial effects upon health owing to an insufficiency of supply for sanitary purposes. Another witness, a midwife, said she had attended a confinement on Aug. 10th when there was practically no water at all to be had. She had not enough on

Digitized by Google

one occasion to wash her hands with. Laundresses testified to the supply having become so short that their business had come to a standstill. Others stated that while there was a scarcity of water in the residences of the neighbourhood of Hackney, there was plenty of water supplied all the time at a certain cow-yard. The inquiry was adjourned soon after three o'clock, the cross-examination of the medical and sanitary witnesses being reserved until Wednesday, when they were examined chiefly on the question of the abolition of cisterns and as to whether the scarcity of the supply had any substantial effect upon the health returns.

THE MEDICAL OFFICER TO THE ARCHBISHOP'S ASSYRIAN MISSION.

WE referred some little time ago in our columns to the need which existed for a medical officer for this mission, and are glad to be able to say that Mr. H. H. Tidswell, formerly house surgeon at St. George's Hospital, left England on Thursday, the 3rd, for Urmi, in Persia, to take up the necessary duties. An attempt will be made to establish a small hospital, which is estimated to cost about £400. Any person desirous to subscribe may communicate with the Rev. R. M. Blakiston, 7, Dean's-yard, Westminster.

ELECTION OF THE MELBOURNE HOSPITAL STAFF.

THE *Age* devotes nearly a column to an account of the election of the honorary staff of the Melbourne Hospital, as if it were a municipal or parliamentary one. The election recurs every four years. We do not admire the system, and doubt very much whether it is calculated to secure the best men. Be this as it may, the exhibition of all the arts of electioneering over the choice of scientific officers is unseemly. But it is provoked by this method, where thirty-one medical men seem to have competed for eighteen appointments, and those who had been in office were threatened with displacement. Fortunately, the good sense of the constituency prevailed over the vices of the method, and the old staff, with one exception, were re-elected. A reasonable term of service should be granted to officers when once elected.

THE MALARIA PARASITE.

WE adverted not long ago to a telegraphic announcement which appeared in the *Times* to the effect that Surgeon-Lieutenant-Colonel Lawrie, as the result of his investigations, had arrived at the conclusion that there is no parasite in the blood in malaria—a conclusion, it need scarcely be added, at variance with the researches of Laveran, Marchiafava, and quite a number of independent observers in this country, America, and elsewhere. We learn that Surgeon-Lieutenant-Colonel Lawrie was assisted in his work by Surgeon-Captain P. Hehir of the Indian Medical Service, by Mr. Martyn Jordan, and by Dr. Conolly from Melbourne, who was temporarily present at Hyderabad. The investigations were begun on June 8th and were continued daily until Aug. 15th last, being, it is stated, conducted both with fresh blood and with stained preparations, on the methods and according to the formulæ usually followed. As many as 116 cases were investigated. We have not yet seen any copy of the report on the subject, and our information, which is therefore necessarily incomplete, is drawn from an article which was recently published in the *Times of India*. The results of the inquiry are that the investigators allege they have established that the microscope is misleading and useless in the diagnosis of malaria, and that there is no parasite in the blood in that disease. "There is nothing in pure blood but hæmocytes and leucocytes—red corpuscles and white cells." The so-called parasite of malaria is nothing more than the blue-stained nucleus of the leucocyte—the white cell. It is stated, further, that the appearances which Laveran and others have pronounced to be malarial parasites are to be found in the blood in health and disease. The full report on the subject will be awaited with curiosity and will no doubt receive a very critical consideration when it appears.

THE LATE SIR THOMAS LONGMORE, C.B.

NOT only members of the military medical services of this country but also medical officers of other countries will hear with extreme regret of the death of Surgeon-General Sir Thomas Longmore, for so many years the well-known Professor of Military Surgery at the Army Medical School, Netley. We can only refer very briefly now to the lamentable occurrence, reserving for another opportunity the publication of a memoir of Sir Thomas Longmore's life and work. The deceased officer had not only a record of distinguished service in the field, having served throughout the Crimean campaign and in Bengal during the Indian Mutiny, but he was conspicuous for his scientific labours in military surgery and in other directions appertaining to military service and war. His work on "Gunshot Injuries" has been long regarded as the standard one on the subject, and it was only the other day, as it were, that a new edition—rendered necessary by the vast and revolutionary changes which have taken place in the art of war—was published. His "Treatise on the Transport of Sick and Wounded Troops" and his "Optical Manual" are recognised handbooks. He was highly esteemed for his personal qualities and character as well as for his scientific attainments, and his sudden death at Swanage on the 1st inst. will be regarded as a distinct loss by the Army Medical Service and by his many friends.

MEDICINE AND MISSIONARIES.

IT was only fitting that the London Missionary Society, which celebrated its centenary in London last week, should devote an afternoon to a discussion on medical work and its place in the missionary scheme. But while the value of their work is acknowledged by all who are in a position to know, it is to be deeply regretted that medical missionaries are not supplied with the necessary means to enable them to carry on their work in a proper manner. Too often they are sent out with a totally inadequate supply of drugs and instruments, and, more regrettable still, the want of proper hospital accommodation often makes their work abortive. This is especially the case where surgical operations are necessary. Something has been done by medical men themselves to remedy this state of things, and the Medical Missionary Society in connexion with St. Bartholomew's Hospital, which was started with the object of keeping those students who leave the institution for the mission field in touch with their hospital, collects funds and gives grants to enable the missionary to equip himself in a more thorough manner than the funds from the various missionary societies will allow. We recently heard of a case where a medical missionary not only practised his profession and attended to the spiritual needs of his patients, but was actually obliged to collect funds from the natives to enable him to carry on his work.

TRUSTWORTHY OINTMENT BASES FOR ANTISEPTIC USE.

AN important contribution relating to the actual disinfectant or antiseptic value of ointments has recently been published by Dr. Breslauer. Several well-known ointment bases containing various antiseptics were employed in experiments and their efficacy adjudged by their effects upon the bacillus prodigiosus and the staphylococcus pyogenes aureus. It was found that the latter organism survived

Digitized by Google

immersion in ordinary carbolised oil (5 per cent. carbolic acid) for three days, in carbolised vaselin only one day, in fat four hours, in lanolin thirty minutes, and in unguentum leniens twenty minutes. Similar results were obtained in experiments with other organisms as well as with other antiseptic agents. Unguentum benzoatum and unguentum precipitatum proved to be powerfully antiseptic, while unguentum zinci exerted no germicidal action whatever. It would thus appear that the only trustworthy ointment bases for antiseptic purposes are those which contain or which will absorb water, as does lanolin or cold cream. It is desirable, of course, also, that the oil or fat employed should be free from any tendency to become rancid, since it is known that zinc ointment in cases where the fatty vehicle has become rancid has proved a dangerous application to open sores, possibly because of the presence of staphylococcus pyogenes aureus. The interesting results which Dr. Breslauer has obtained suggest that the oleaginous particles of certain bases serve as an effective barrier between the active antiseptic agent and the organism. This explanation is the more probable since the best germicidal effects were obtained when fats or oils containing moisture were employed; besides which, experiments have been set on foot which have shown, in the case of carbolised oil, for example, that the oil remained intact and had not volatilised or undergone any change.

SUCCESSFUL REMOVAL OF A CEREBRAL TUMOUR.

THERE is, we believe, an impression abroad that cerebral surgery has undergone an eclipse, and, while it is true that our hopes and expectations with reference to it are less sanguine than they were a few years ago, yet much is still being done, and in not a few instances the operations are crowned with a success which is in the highest degree gratifying. In the last number of the *Neurologisches Centralblatt* an abstract of a case published by Dr. Gajkiewicz is given, and it is especially interesting and important, because apparently the tumour removed was a syphilitic one. The patient had no obvious signs of syphilis, but complained of constant severe pain in the right temporal region, increased by pressure or tapping. Ten years before he had received an injury to the right frontal region, and two months before an injury to the right temporal region, which had apparently been the starting-point of the present pain. He had typical attacks of left-sided Jacksonian epilepsy, with subsequent weakness of that side of the body. The fits always commenced in the upper extremity, and were frequently ushered in and accompanied by a feeling of pain, heat, and burning. The optic discs were a little obscured and the veins very large. There were enlarged glands in the neck, and a few months before there had been a swelling on the skull which had spontaneously disappeared. Energetic antisyphilitic treatment produced only temporary improvement, which was followed by an increase in the intensity of the symptoms. The attacks became more frequent and more severe, and were often accompanied by loss of consciousness. Trephining was performed over the right hemisphere at a point corresponding to the centre for the upper limb and face. A tumour was removed, which microscopic examination showed to be gummatous. After this, as many of the slighter symptoms still persisted, antisyphilitic treatment was again pushed and the patient completely recovered from all his symptoms.

THE "SOUGHS" OF DERBYSHIRE.

NOW that the cry for more and better water is being raised in all the larger towns Dr. Barwise's report on the "soughs" or old drains of the disused lead mines in the Peak district, though of specially local interest, is suggestive of the probable existence of untried sources of like extent in other parts of the mountain limestone. At present these soughs have not been impounded and appropriated for the supply of towns while still uncontaminated by sewage and factory wastes, but are allowed to run off into the Derwent and other rivers, though they might be utilised with the minimum of expense, yielding enormous volumes of water at altitudes rendering pumping unnecessary. The "Magpie Level," which empties into the Wye near Bakewell, yields 9,000,000 gallons daily, and the "Hill Car Sough" pours 6,000,000 gallons into the Derwent near Rowsley. The "Merebrook Sough" discharges 13,000,000 gallons a day into this river near Ambergate, and the "Wakebridge Sough" close by 4,000,000 gallons, though this last is almost a thermal spring, having a temperature of 62° F. These four alone would afford an ample supply for a population of over a million persons, and would be a special boon to the rural district authorities, to whom costly waterworks are an impossibility. Though derived from worked-out lead mines, the waters are entirely free from that metal, probably because the lead which remains is in an insoluble form, at any rate in waters of such hardness; whereas the peaty waters of the Yorkshire moors are notorious for their solvent action on lead pipes. In these soughs there are wells already sunk, but, as geologists know well, the mountain limestone everywhere contains vast subterranean reservoirs of splendid water, which have only to be found and tapped to yield rich supplies distributable by gravitation. It was one of these which flooded the Severn Tunnel when in course of construction, and which has ever since been allowed to run to waste into the tidal river. Mountain and moorland districts, while providing excellent collecting areas, are for the most part so remote from the great centres of population that the low price at which the land or water rights can be secured is counterbalanced by the cost of conveyance through conduits of perhaps a hundred miles in length; and to neglect natural sources of water of undoubted purity, while vainly attempting to purify that taken from sewage-polluted rivers, is culpable and utterly unreasonable.

THE town council at their last meeting elected to the post of medical officer of health and public analyst for the borough of Leicester, in place of Mr. Joseph Priestley, B.A., M.D., D.P.H. (now medical officer of health of Lambeth), Mr. H. G. H. Monk, M.R.C.S., L.S.A., D.P.H., Mr. Monk is at present medical officer of health and public analyst of Scarborough, a position he has held for the last three years, and he was formerly assistant to Dr. Thursfield, medical officer of health of Shropshire county.

THE Abernethian Society of St. Bartholomew's Hospital will open its 101st session on Thursday, Oct. 10th, when Dr. Church will deliver the introductory address at 8 P.M in the Anatomical Theatre. The subject will be the Rise of Physiology in England and its Effect on the Practice of Medicine.

THE annual dinner of past and present students of Charing-cross Hospital will be held in King's Hall, Holborn Restaurant (Newton-street entrance), on Wednesday, Oct. 23rd, at 6.30 for 7 P.M., when Mr. C. Jerome Woollett, M.B. Lond., F.R.C.S. Eng., will take the chair.

THE President will not deliver the Presidential Address at the first meeting of the Pathological Society on Oct. 15th. He proposes to deliver his address next year, when the society will celebrate its fiftieth anniversary.

AT a recent meeting of the trustees of Jefferson Medical College, Philadelphia, the honorary degree of LL.D. was conferred on Dr. John Collins Warren, Professor of Surgery in Harvard University.

Digitized by Google

OPENING OF THE MEDICAL SCHOOLS.

MOST of the London medical schools, whether the formal introductory address to students has fallen into desuetude or no, have inaugurated their winter session with a dinner, attended by the past and present students, or by some other social gathering. We give a brief account of the proceedings.

ST. GEORGE'S HOSPITAL.

The annual dinner of the St. George's Hospital Medical School took place at the Whitehall Rooms, Hôtel Métropole, on Oct. 1st. Mr. George Pollock (the orator of the day), Mr. Holmes (the treasurer of the hospital), Dr. Howship Dickinson, a large number of the medical staff, and several influential governors were present, together with a large and representative gathering of past and present students. Dr. Blandford was in the chair, and conducted the proceedings with great tact and eloquence. The usual patriotic toasts and those of "The Governors," "The Medical School," "Past and Present Students," &c., were received with enthusiasm. Dr. Dickinson spoke of the immense amount of work done by the school for the hospital, and suggested that at least the governors should give it house-room in return. Mr. Holmes said that the relations of the governors and the school were of the utmost cordiality, and referred the previous speaker to the quarterly court. He then spoke of his delight in being able to serve the hospital as treasurer now that he was no longer on the active staff. Mr. Warrington Haward dwelt on the admirable and unostentatious work done by the resident hospital staff, and pointed out that often enough the conducting of a serious case to a successful issue was really due more to the assiduous care of the house surgeon and nurses, than to the efforts of the surgeon in charge whose name figured above the bed. Dr. Isambard Owen, the dean of the school, spoke of the flourishing state of that institution. The examination results were highly satisfactory, and the athletic record deserved great praise. The present entry was very large, and might even break the record. It was stated that the Directory of St. George's Hospital men was ready, and would shortly be published. In looking up the lists of past house surgeons for publication the first name found was that of John Hunter. A most enjoyable and enthusiastic evening was brought to a close by a musical sketch, admirably given by Mr. Mercer Adam, a sometime student.

LONDON HOSPITAL.

The Old Students' Annual Dinner was held on Oct. 1st at the Criterion Restaurant instead of, as in former years, in the library of the London Hospital Medical College. About 130 attended the dinner. In the unavoidable absence of Mr. Couper, who was to have presided, the chair was taken by Dr. Stephen Mackenzie. In proposing the toast of the evening, he mentioned the fact that the present session was the 111th anniversary of the opening of the London Hospital Medical School. He briefly traced the progress of the medical school as evidenced by the successive occasions on which it had been found necessary to enlarge the college buildings, especially in 1854, 1871, 1879, and 1885. Quite recently the physiological laboratory had been doubled in size. He referred at some length to the question of medical education in London, and advocated the endowment of medical teaching. Mr. Treves followed with an amusing speech, in which he ridiculed the notion that the opening of the winter session could be properly marked by so frivolous a process as eating, and humorously suggested that the occasion would be more fittingly celebrated by a procession of the staff, students, and nurses, in fancy dress, along the Mile End-road. Old London Hospital men who were unable to be present at the dinner will be glad to know that the entry for the summer session was greater than on any previous occasion and that for the present session very much greater than at the corresponding period last year.

ST. BARTHOLOMEW'S HOSPITAL.

The annual old students' dinner was held on Oct. 1st in the great hall of the hospital, the number of guests being about 125. The chair was taken by Mr. Howard Marsh. After the usual loyal toasts the chairman proposed "The Health of the Hospital and School" in an amusing speech, in which he compared the hospital routine of the present day with that of the Middle Ages. Dr. Hensley also, in responding to the toast of his health, afforded the company an intellectual treat. Among the guests present were Sir James Paget, Sir George Humphry, Professor Burdon Sanderson, Professor Clifford Allbutt, the Dean of Christchurch, the Master of Downing, Dr. Rutherford, headmaster of Westminster School, and Sir Trevor Lawrence. Several of these also spoke.

WESTMINSTER HOSPITAL MEDICAL SCHOOL.

The introductory lecture was given at 4 P.M. by Dr. Monckton Copeman, which was followed by a report from the dean, Mr. Spencer. Owing to the enforced absence of Viscount Peel, the prizes were distributed by Dr. Potter, who concluded with a few happy remarks to the students. The annual dinner of the medical school took place at the Café Monico on Tuesday, Oct. 1st. The chair was taken by Dr. de Havilland Hall, physician to the hospital. As usual, most of the members of the staff were present, and the House Committee was represented by Mr. G. G. Tremlett, who with Mr. W. G. Spencer, the dean of the medical school, responded to the toast of "The Medical School and Hospital," which was proposed by the chairman. The other toasts were "Royalty," "The Old Students," and "The Chairman." The proceedings were enlivened by the strains of a string band, and the result was a most satisfactory evening's entertainment.

UNIVERSITY COLLEGE HOSPITAL.

The annual dinner of the past and present students of this hospital was held at the Hôtel Métropole on Tuesday, Oct. 1st, Sir Richard Quain, F.R.S., being in the chair. The gathering was a very successful one. The President of the General Medical Council was supported by the President of the Royal College of Physicians of London and the President of the Royal College of Surgeons of England, and it is a remarkable coincidence that all three Presidents were either connected with University College Hospital in the past or are at the present time. The chairman, in giving the toast of the evening, remarked that he had entered as a student when the hospital had only been three years in existence, and gave some interesting reminiscences of a number of distinguished men who had been connected with it. He said that University College had exercised an important influence on medical education generally, for not only had its methods of teaching been largely imitated, but at the present time no less than thirty-six former alumni of University College were teachers in other metropolitan medical schools.

MIDDLESEX HOSPITAL.

The annual festival was held on Oct. 1st at the Café Royal and was a great success. There was a very large attendance of old and present students and Dr. Cecil Y. Biss was in the chair. After the customary toasts of "The Queen and Royal Family" and "The Services" Dr. Biss proposed the toast "The Middlesex Hospital and Medical School." He alluded to the necessity of a close connexion between these two elements and felt sure that under the present circumstances the sympathies of the two were becoming closely bound up in each other. He alluded to the energies of the chairmen of the hospital, mentioning the names of Mr. Ross, Lord Sandhurst, and the present chairman, Sir Ralph Thompson. Some allusion was also made to the great loss which the hospital has sustained in the death of Mr. Hulke, and also to another gap which will soon occur by the contemplated retirement of Mr. Lawson. Dr. Biss, however, expressed his full belief in the future prosperity of Middlesex Hospital, and mentioned some of the great improvements which have lately taken place, among which may be mentioned the new operating theatre, the new convalescent home, and the erection of new cancer wards. Sir Ralph Thompson, in reply, fully endorsed Dr. Biss's remarks, and expressed his great desire to see a close bond of sympathy between the lay and medical workers of the hospital. He also referred to the efficient working of the hospital, for which much credit was due to Mr. Farden, Mr. Melhado, and Miss Thorold. Mr. Pearce Gould also replied to the chairman's toast, and referred to the many improvements in medical teaching which have taken place in the last few years, and regretted that the scheme for a new University for London had not made more definite progress. "The Past and Present Students" was ably proposed by Mr. Lowne. Dr. Newman, in reply for the past students, expressed his great satisfaction at seeing so many old students there, and expressed the confidence he

Digitized by Google

felt in recommending fresh students to go under the care of the present staff. Mr. Braine Hartnell, for the present students, gave a good account of the state of the school both in games and work. In thanking the staff for all their help and kindness, he ventured to suggest the hope that they would see their way to abolish the fee which is now paid on holding resident appointments, which he thought fell as a burden on many students. In alluding to the games he gave a brief account of the past doings, and expressed a belief and hope that the athletic side of the school was constantly improving. Dr. Duncan proposed "The Visitors," coupled with the name of Mr. Ganz, who has been such a regular visitor to the Middlesex Hospital dinners for so many years. Mr. Ganz expressed his thanks for himself and the other visitors, and said what a great pleasure these meetings gave him, and that he always was very pleased to come. Dr. Douglas Powell proposed the health of the chairman, and alluded to the long connexion and valuable services which Dr. Biss has rendered to the Middlesex Hospital. This toast, the last of the evening, was enthusiastically responded to and a very pleasant evening was terminated. Much of the success of the evening was due to the charming music rendered at intervals by Mr. Bernard Law, Signor Giuseppe Maggi, Mr. Irving, Mr. Myler, and Mr. Wilhelm Ganz.

KING'S COLLEGE HOSPITAL.

The annual dinner of the old students of King's College Hospital was held at Limmer's Hotel on Tuesday, Oct. 1st, and formed a pleasant inaugural meeting for the commencement of the session. Dr. Robert Shingleton Smith of Bristol occupied the chair, and he was supported by a very large and representative gathering of old students of all ages. In proposing the toast of the evening, "Success to King's College Hospital and its Medical School," Dr. Shingleton Smith said that it was most satisfactory to look around and consider the great distances men did not mind travelling to attend these dinners. There were representatives from Yorkshire, from Exeter, from Bristol, from Birmingham, and from Tredegar; they came not only to meet old friends, but to hear their accounts of others who might not be present, and to rejoice in their successes and in the lustre they conferred upon King's College even when shining from a distance. As recent causes of congratulation he instanced the election of Mr. Christopher Heath as President of the Royal College of Surgeons of England, of Dr. Brodie as Lecturer on Physiology at St. Thomas's Hospital, and of Sir Joseph Lister as President of the British Association for the next annual meeting. In felicitous terms he mentioned the use of the College buildings for the recent meeting of the British Medical Association, the large hall having been used for the reception-room. After many reminiscences of his own student days he concluded by referring to the King's College Hospital Reports, which already included subscribers from India, China, Australia, and Hawaii. Deputy-Surgeon-General Jessop responded to the toast of "The Army, Navy, and Reserve Forces," and speeches were also made by the Rev. Dr. Wace, Dr. Lionel Beale, Dr. Allfrey of St. Leonards, Mr. Richardson Cross of Bristol, Dr. Playfair, and Dr. Curnow. During the evening Mr. Percy L. Webster and Mr. A. Schartau contributed a selection of songs which were much appreciated.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.

At 3 P.M. on Wednesday, Oct. 2nd, there was a large gathering in the Governors' Hall of those interested in the school and hospital, when the prizes and certificates of the past year were distributed by Sir Edwin Arnold, K.C.S.I. After the distribution of the prizes Sir Edwin Arnold gave a brilliant address, which was much appreciated, and which is published in another column of our present issue. The annual dinner of old and present students was held in the evening, at 7 P.M., at the Whitehall Rooms of the Hôtel Métropole. Dr. Payne was in the chair, and about 140 persons were present, including guests. The speeches were good and the toast list not too long. After the usual loyal toast, Dr. T. B. Crosby proposed "St. Thomas's Hospital and Medical School (past and present)," which was acknowledged by the Treasurer of the Hospital (Mr. Wainewright), the Dean of the Medical School, Mr. Makins, and Mr. George Rice Ord. Dr. W. M. Ord proposed "The Chairman," a toast heartily received, and Dr. Payne replied. Mr. W. H. C. Staveley proposed "The Hon. Secretaries," and Dr. Toller and Mr. Abbott replied. The dinner was a great success, and the arrangements reflect great credit on the secretaries.

ST. MARY'S HOSPITAL MEDICAL SCHOOL.

The dinner of the past and present students was held at the King's Hall, Holborn Restaurant, on Oct. 1st. Mr. Malcolm Morris presided. Among those present were Sir William Broadbent, Mr. Norton, Dr. Cheadle, Mr. Edmund Owen, Dr. McCall Anderson, General Shaw Stewart, R.E., Colonel Bird, Mr. Page, Dr. Lees, Mr. Critchett, Mr. Silcock, Dr. Phillips, Major Hanbury White, R.E., Dr. Danford Thomas, Mr. John Moore, J.P., Dr. Luff, Surgeon-General Jeffcoat, Mr. Hetherington, Dr. Franklin Parsons, Mr. Havell, Dr. Walter, F.R.S., Dr. Symes Thompson, Dr. Handfield Jones, Surgeon-Major Hayes, Surgeon-Captain G. E. Hale, &c. The chairman proposed "The Navy, Army, and Reserve Forces," and the toast was responded to by Fleet-Surgeon T. J. Preston, R.N., Brigade-Surgeon-Lieutenant-Colonel Myers, and Surgeon-Lieutenant-Colonel Norton. The chairman, in proposing the toast of the evening, gave an amusing sketch of an interview between an old student of thirty years ago and one of the present time, showing the vast change in the class of men who now enter the profession. St. Mary's had increased in numbers, and this was due to the energy of the Dean (Mr. Field). The Dean replied and Dr. Wills responded for the "Past" and Mr. Thorne for the "Present Students." The staff was represented by Sir William Broadbent, who proposed the chairman's health. A delightful evening was brought to a close by an excellent selection of music and songs by Messrs. Schartau, Fell, Appleby, Bradford, and J. E. Lane, and a ventriloquial sketch by Mr. F. Russell.

ROYAL VETERINARY COLLEGE.

Professor Penberthy, who delivered the introductory address at the Royal Veterinary College, said the systematic teaching of veterinary science in Great Britain dated from the foundation of the college in 1791 by Vial de St. Bel, a French veterinary surgeon. In its infancy the interests of the school were fostered and its honour added to by the cöoperation of the most eminent medical men. Justifiable pride mingled with grateful sentiment while acknowledging the indebtedness of the college and profession to the early examining committee, whose roll was adorned by such names as Astley Cooper, Blizzard, Horne, J. Abernethy, Brodie, C. Bell, J. H. Green, and Coleman. Referring to the bearing of veterinary science on the welfare of the general community, Professor Penberthy remarked that before the establishment of a State veterinary department and the adoption of the teachings of veterinary science, an invasion of cattle plague reduced the financial resources of the country to the extent of millions of pounds. An incursion of sheep-pox was scarcely less costly. Foot-and-mouth disease in some years affected nearly 700,000 animals. Pleuro-pneumonia for a long time cost the country little short of £50,000 annually. Those affections were now regarded as exotic, but kept from our shores only by strict adherence to the teachings of veterinary science. If the protection provided by veterinary knowledge were withdrawn, the flickering light of agriculture, the leading industry of this country, could scarce escape extinction. Under the watchful care of a veterinary department, the supply of cheap animal food was assured to the people without danger of special loss to one part of the community from the invasion of imported contagious disease, for until within a few years of the formation of the Department the law prohibited the importation of live stock. Under all these circumstances it was a cause for wonder that the act of any Government should appear to hold its worth so cheap as to extirpate the word veterinary, which has described the Department for thirty years, and to render it appparently subordinate and declining in value. By increased knowledge of animals and their diseases, by use of anæsthetics and improved methods in surgery, animal suffering had been materially lessened and animal service increased.

UNIVERSITY OF DURHAM COLLEGE OF MEDICINE.

The opening of the session took place in Newcastle-upon-Tyne on Tuesday, Oct. 1st. The meeting was presided over by the President of the College of Medicine, and there was a large attendance of the public interested in the college. The Warden of the University (the Very Reverend Dr. Kitchin, Dean of Durham) distributed the prizes and scholarships to the successful students. The Mayor, Sheriff, and other members

Digitized by Google

of the corporation were present, and among the guests were the heads of houses and other dons from Durham, the Principal of the Durham College of Science, the High Sheriff of Durham, the Nestor of the Profession in Newcastle, Dr. Embleton, the Mayor of Durham, Dr. Jepson, and many other well-known and prominent citizens. The students were, as usual, very much in evidence, but on the whole the proceedings passed off unusually quietly. The President, Professor Philipson, after welcoming the warden on his first appearance at an opening of the College of Medicine, alluded to the new charter enabling the University to grant degrees in medicine and in all the other faculties, with the exception of Divinity, to women, and to hold convocations in Newcastle. He announced that the first convocation would be held in the examination hall of the College of Medicine in April next.

On Tuesday evening, at the Hôtel Métropole, Newcastle-upon-Tyne, some eighty old students of the University of Durham College of Medicine dined together. Professor Arnison, who, with the exception of Mr. J. A. Angus, was the oldest student present, presided, and a very pleasant evening was spent. Much credit is due to Dr. W. D. Arnison and to Mr. Walter Ridley, the secretaries of the dinner committee, for the admirable way in which the arrangements were carried out, and it is hoped the dinner will become an annual one.

LIVERPOOL UNIVERSITY COLLEGE.

The opening of the winter session of the Medical Faculty of the Liverpool University College took place on the 1st inst., under most favourable auspices. Lord Derby, the President of the College, presided, and was supported on the platform by the Lord Mayor of Liverpool (Mr. W. H. Watts), Mr. Edward Lawrence, chairman of the council, the professors of the College, and leading citizens. There was also in addition to the students a large attendance of ladies and gentlemen. Professor Paterson, the Dean of the Medical Faculty, presented his report, which indicated considerable activity in the growth of the Faculty during the last twelve months. The number of students attending classes in the winter session, excluding those taking out hospital practice alone, was 146. During the winter session the new entries were 56, and during the summer session the numbers were 127, including six new entries and seven new entries for special courses. The two facts noticeable on making up this summary were that the numbers in the school generally were practically stationary, the number of diploma students was diminishing, while the number of university and dental students was increasing. In this connexion it might be added that a very desirable addition to the attractions of the school would be the establishment of a hall of residence within easy reach of the college. Summarising the results of professional examinations, 118 students had passed examinations—108 medical, 10 dental. Lord Derby then distributed the medals and prizes awarded by the Medical Faculty.

CALENDAR OF THE ROYAL COLLEGE OF SURGEONS OF ENGLAND.

THE annual Calendar has just been published by the Council of the College. It shows that there are 1160 Fellows on the roll of the College (against 1144 last year), of whom 947 obtained the Fellowship by examination, 16 were elected as Members of twenty years' standing under Section 5 of cap. 15 Vict., and 2 are *ad eundem* Fellows. There are 16,816 Members and 645 Licentiates in Midwifery. The Licentiates in Dental Surgery are stated to number 1007. The holders of the diploma of Public Health number 215.

During the past collegiate year 577 candidates presented themselves for examination in Elementary Anatomy, of whom 473 passed and 104 were referred; 82 candidates presented themselves in Elementary Physiology, 55 of whom passed and 27 were referred; 488 candidates presented themselves in Elementary Biology, of whom 327 passed and 161 were referred. The examiners are appointed in conjunction with the Royal College of Physicians of London, under the scheme for an Examining Board in England. The fees paid by candidates for these examinations amount to £2991 3*s.* 9*d.*, the examiners receiving in fees £431 5*s.* Of 609 candidates who presented themselves in Chemistry, 355 passed and 254 were referred; in Materia Medica, of 258 candidates 178 passed and 80 were referred; in Practical Pharmacy, of 226 candidates 181 passed and 45 were referred. The examiners in Chemistry, Materia Medica, and Practical Pharmacy are elected by the Royal College of Physicians of London.

The examiners in Anatomy and Physiology for the Second Examination are appointed in conjunction with the Royal College of Physicians of London; they have conducted the Primary Examination under the old regulations as well as the Second Examination of the Examining Board in England; 811 candidates presented themselves for examination in Anatomy, of whom 433 passed and 378 were referred; 803 presented themselves in Physiology, 454 of whom passed and 349 were referred. The fees paid by candidates for examination amounted to £3726 9*s.*, the examiners receiving £1329 2*s.*

The Board of Examiners in Anatomy and Physiology for the diploma of Fellow, elected annually by the Council, held two meetings for the examination of 171 candidates, of whom only 63 passed, whilst 108 were referred. The fees received amounted to £1050, of which the Board received £684.

The Court of Examiners, ten in number, are elected by the Council from the Fellows of the College only, for a period of five years. They conduct the Third or Final Examination in Surgery of the Examining Board in England as well as the Second or Final Examination for the diploma of Fellow. During the past collegiate year the Court held two examinations for the Fellowship and four for the Membership; at the former there were 79 candidates, 45 of whom passed, 4 were referred for one year, and 30 for six months. For the Membership 937 candidates presented themselves in Surgery, of whom 579 passed and 378 were referred. The fees paid by candidates amounted to £10,142 3*s.*, and the fees paid to the Court of Examiners and the examiners in Midwifery amounted to £5697 13*s.* The examiners in Medicine under the scheme are elected by the Royal College of Physicians of London. Of 905 candidates examined, 521 passed and 384 were referred. The examiners in Midwifery are appointed in conjunction with the Royal College of Physicians of London, and have examined 824 canddates, of whom 558 passed and 266 were referred.

The Board of Examiners in Dental Surgery have held two meetings for the examination of 121 candidates, 84 of whom received the diploma and 37 were referred. The fees paid by candidates amounted to £882, the Board receiving £512 8*s.*

The examiners in Public Health, appointed in conjunction with the Royal College of Physicians of London, examined 53 candidates in Part I., 35 of whom passed and 18 were referred; in Part II., out of 46 candidates 26 received the diploma and 20 were referred. The fees received for both parts amounted to £234 13*s.* 6*d.*, the examiners receiving £186.

With regard to the finances of the College, it appears that the income from all sources amounted to £28,490 8*s.*, the largest item being derived from the fees paid by candidates for the diplomas of the College—viz., £18,791 15*s.* 9*d.*—the next largest item being from dividends on the Erasmus Wilson bequest, £4813 16*s.* 1*d.*; rents from chambers adjoining the College produce, £750; investments, £750 2*s.* 8*d.*; hire of rooms and sale of questions at Examination Hall, £680 17*s.* 3*d.*; fees retained for referred candidates, £334; from trust funds, £279 9*s.* 5*d.*; incidental receipts, sale of calendars, &c., £14 1*s.*; sinking fund, £2 5*s.* 11*d.*; Goldsmiths' Company Research grant, £500; balance at bankers, 1894, £1578 0*s.* 2*d.*

The expenses for the year amount to £27,760 11*s.* 3*d.* (leaving a balance at the bankers of £729 16*s.* 9*d.*), the largest item being for fees to examiners, £8840 8*s.*; expenses of examinations (Fellowship and dental only), £342 7*s.* 1*d.*; half expenses examination hall, £4519 9*s.* 5*d.*; half expenses, research laboratories, £825 18*s.* 11*d.*; rates, taxes, and insurance, £1540 12*s.* 10*d.*; extraordinary expenses, £298 1*s.* 10*d.*; alterations and repairs, £669 5*s.* 8*d.*; fees to Council, £240 9*s.*; salaries, wages, and pensions in the three departments (museum, library, and College), £4693 6*s.* 2*d.*; lectures, catalogues, specimens, &c., for museum, £673 11*s.* 9*d.*; purchase of books, &c., for library, £653 9*s.* 4*d.*; trust funds, £302 3*s.* 10*d.*; fees returned to candidates, £556 10*s.*; purchase of stock, £2150 15*s.* 7*d.*; expenses, Metropolitan Asylums Board (repayable) £186 5*s.* 9*d.*; miscellaneous items—i.e., fuel, light, printing, stationery, &c.—£1267 17*s.* 11*d.*

From the librarian's report it appears that the supply of new books has been well kept up during the present year.

Digitized by Google

The donations include the MS. material for a Greek medical lexicon prepared by the late Dr. Greenhill (presented by Miss Greenhill), a collection of pamphlets from Sir Henry Acland, several old books from Mr. Alfred Kisch, and a MS. report of John Hunter's lectures from Mr. C. Leeson Prince. The copper and steel plates used for printing Mr. Joseph Swan's book on the "Nervous System" have been presented by Mrs. J. V. Machin of Gateford Hill, Worksop. Exchanges have been made with the British Medical Association and the Medical Society of Victoria. Amongst the old books purchased may be mentioned a copy of the rare (1672) "Treatise of Wounds" by Richard Wiseman. The collection of portraits has received a valuable addition from Mr. Jabez Hogg in the shape of a series of daguerreotypes of eminent physicians and surgeons taken by him nearly fifty years ago. Mr. Hogg has also presented a portrait in oil of a surgeon (name unknown), dated 1677, and several volumes of interesting pamphlets. Including journals and Transactions the total number of volumes in the library is about 48,000.

Amongst the additions to the Museum may be mentioned a sarcoma of the patella; a roll of hair weighing five pounds successfully removed by operation from the stomach; and an enlarged spleen in a child, which weighed one-sixth of the whole body's weight. Mr. Willoughby presented a humerus taken from an Egyptian skeleton dated about 4000 B.C., and in addition to its antiquity it is of interest as showing an old injury to the head of the bone which must have produced considerable deformity of the limb. An important addition to the Museum is that of 205 skulls and crania, with 40 models, purchased from the Anthropological Society.

The Secretary's report deals with the following subjects: an abstract of the work done by the Council and committees; the work of the Committee of Management of the two Royal Colleges; particulars concerning the Research Laboratories on the Victoria Embankment; reports of meetings of Fellows and Members; results of elections &c.

MEDICO-PSYCHOLOGICAL ASSOCIATION OF GREAT BRITAIN AND IRELAND.

THE fifty-fourth annual meeting of the Medico-Psychological Association of Great Britain and Ireland was held on July 25th and 26th, under the presidency of Dr. D. Nicolson, at the rooms of the Association, 11, Chandos-street, Cavendish-square. The proceedings commenced at eleven o'clock on the first day with the election of officers and the transaction of general business. Dr. H. Rayner was elected Editor of the *Journal of Mental Science* in place of the late Dr. Hack Tuke, and it was decided that the Association should be incorporated. In the afternoon the President took the chair and after presenting an illustrated memorial and silver bowl to Dr. J. H. Paul, who had been treasurer of the Association for thirty-one years, delivered an address on Crime, Criminals, and Criminal Lunatics. His remarks on crime, interesting in themselves, were rendered still more so by a number of statistical tables. He did not believe that men who became criminals were born so and could not help themselves. From his experience as a prison medical officer many years ago he was of opinion that, though there were a certain number of weak-minded criminals who in the face of temptation were unable to resist it and thereby became criminal, yet in the large majority of cases criminality shows itself as a positive propensity to evil-doing. Cases like these are not unintelligent and are quite capable of balancing motives, but deliberately, and in spite of their consciousness of its risk, prefer crime to an honest livelihood. He agreed with a large part of the phraseology and descriptions which Lombroso and others had given, but these descriptions applied to a minority of criminals only. He objected to a description which was applicable to the few being held up to the world as a description applicable to the characteristics of the whole body. He denied that there was such a thing as a criminal neurosis or instinctive criminality that belongs to a group of persons who make themselves amenable to the law. — Sir Edmund du Cane, Dr. Orange, Dr. Clouston, and Mr. Conolly Norman discussed the views set forth in the address, and the President replied.

Dr. Rivers then read a paper on Experimental Psychology in relation to Insanity, illustrated by an apparatus for measuring choice time. He mentioned that Professor Kräpellin of Heidelberg and his pupils had for some time been working on the application of methods of measuring mental capacity in cases of insanity, and the method he would show would be one of those which Professor Kräpellin used. His methods, to a great extent, resolved themselves into time measurement. The means of measuring work done is to a great extent to measure the time which it takes and the amount of work which can be done in a certain time. Another branch of Professor Kräpellin's work is the investigation of abnormal influences, such as drugs, overwork, and excessive fatigue, on normal people. These abnormal influences are not only recognised causes of insanity, but some of them, such as alcohol, produce conditions identical with those in many forms of insanity. In investigating the effects of these abnormal conditions we are investigating artificial insanities in their earliest stages at a time when they do not come under the notice of the physician. With the assistance of one of the members Dr. Rivers then proceeded to demonstrate the method of measuring choice time which he had described.—The President, Dr. H. Rayner, Dr. Percy Smith, Dr. D. Yellowlees, and Dr. A. R. Urquhart discussed the paper, and Dr. Rivers replied.

On July 26th Dr. Clouston and Dr. Batty Tuke opened a discussion on Rest and Exercise in the Treatment of Insanity. Dr. Clouston was strongly in favour of exercise, as it produced sleep, calmed maniacal and melancholic excitement, and improved the working of the secretory and excretory glandular system. In addition, it promoted healthy metabolism and nutrition, and stimulated the blood-forming glands and apparatus by the circulation of an increased amount of oxygen in the blood. Rest, in the sense of staying in bed for twenty-four hours, he had seen do harm, and was applicable as a therapeutic agent only in cases of extreme neurasthenia, in exhausted conditions such as the puerperal state, and in those suffering from bodily diseases and who are clearly exhausted from over-exertion. Muscular exercise produced brain rest and was the most efficient way of obtaining it. By putting the muscles into exercise we act by way of a derivative from the excited cortex and secure brain rest in a physiological fashion.—Dr. Batty Tuke maintained that in cases of insanity from over-exertion there was hyperæmia of the brain cortex, and that the congestion is properly and rightly treated by rest. He referred to the condition of the brain cells found in the honey-bee in the evening after a hard day's work contrasted with the conditions which are seen in the morning, and maintained that what is wanted in the treatment of the insane is to give rest so that the congestion may be diminished and the cell be renourished and able to return to its original condition. He quoted statistics of forty cases of incipient insanity, half of whom recovered within three weeks and the rest within six weeks under his treatment.—The President, Dr. Rayner, Dr. Blandford, Dr. Rivers, Dr. Cooke, Dr. Drapes, Dr. Yellowlees, Dr. Andriezen, Dr. Urquhart, Dr. Savage, Mr. Conolly Norman, and Dr. Robertson discussed the papers, the conclusion being come to that the means of treatment are to be used with reference to the individual patient, and Dr. Clouston replied.

Dr. Turnbull read a paper entitled "Some Remarks on the Forcible Feeding of the Insane." He was of opinion that it was a mistake to wait until the patient became exhausted, and thought the best apparatus for feeding was the œsophageal tube. Considering the comparatively slight risk entailed, it should be oftener resorted to for the sake of the patient. No form of feeding, however, was absolutely safe unless due precaution was taken. — The President, Dr. Briscoe, Dr. Drapes, Dr. Clouston, Dr. Yellowlees, Dr. Macdonald, Dr. Merson, Dr. Robertson, Dr. Urquhart, Dr. Cooke, Dr. Carlyle Johnstone, Mr. Hayes Newington, Dr. Finegan, Dr. Outterson Wood, Dr. Tuke, Dr. A. S. Newington, Dr. Gramshaw, and Dr. Soutar discussed the paper, and Dr. Turnbull replied.

Dr. W. F. Robertson read a paper on the Pathology of Milkiness, Thickening, and Opacity of the Pia-Arachnoid in the Insane, and exhibited numerous microscopical specimens as an illustration to the paper.

Dr. G. E. Shuttleworth contributed a paper on Provision for Pauper Idiots and Imbeciles. He referred to the want of accommodation for this class of cases and mentioned that, besides the rate-supported institution at Darenth, there were in England only five other training schools, which were all kept up by voluntary contributions. A block for idiots has been erected at the Northampton Asylum, and similar blocks were

Digitized by Google

contemplated at two other asylums, but further accommodation was urgently needed. He advocated the erection of institutions, if necessary by a combination of counties, or the erection of separate blocks in connexion with the existing county or borough asylums.—Dr. Fletcher Beach made some remarks on the paper.

Dr. Clouston read for Dr. L. C. Bruce a paper on Thyroid Feeding. Dr. Bruce advocated its use in (1) cases of melancholia whose improvement had been arrested; (2) cases of mania showing signs of dementia; and (3) cases of stupor at an early stage, in which the effect was to wake them up. The treatment had also been tried on general paralytics and on patients suffering from dementia of forty years' duration. Five-grain tabloids were used, but the heart's action had to be watched and the patient kept in bed all the time in case of heart failure.—Dr. Fletcher Beach made some remarks on this paper.

Dr. Dawson brought forward a paper on a very rare case of Ecchymosis following Insane Excitement, which was discussed by the President, Dr. A. R. Urquhart, and Dr. T. W. McDowall.

On the evening of July 26th the annual dinner took place at the Whitehall Rooms, Hôtel Métropole, Dr. D. Nicolson, president, being in the chair. The loyal toasts having been duly honoured, the President proposed "The Navy, Army, and Auxiliary Forces," to which Major Macbean (in the absence of Sir Frederick Middleton) and Dr. J. H. Paul, ex-treasurer, responded. To the toast of "The Legal Administration," proposed by Dr. Yellowlees, Sir John Bridge, Mr. Kenelm Digby, and Dr. F. Needham replied. The toast of "The Medico-Psychological Association" was proposed by the Right Hon. the Speaker of the House of Commons, who remarked that in the course of the present century enormous steps had been taken in the humane treatment of lunatics. He was glad to hear that the Association had specially taken in hand the training and education of competent nurses and attendants on the insane. He was also glad to hear that the Association was flourishing, that its membership was steadily increasing, and that its members were to be found throughout the whole of their vast empire. The President, in responding, remarked that with regard to the future he was glad to say they had had during their meetings an illustration of the capacity of the rising members of their specialty for taking up the work that had been handed to them. Other toasts followed.

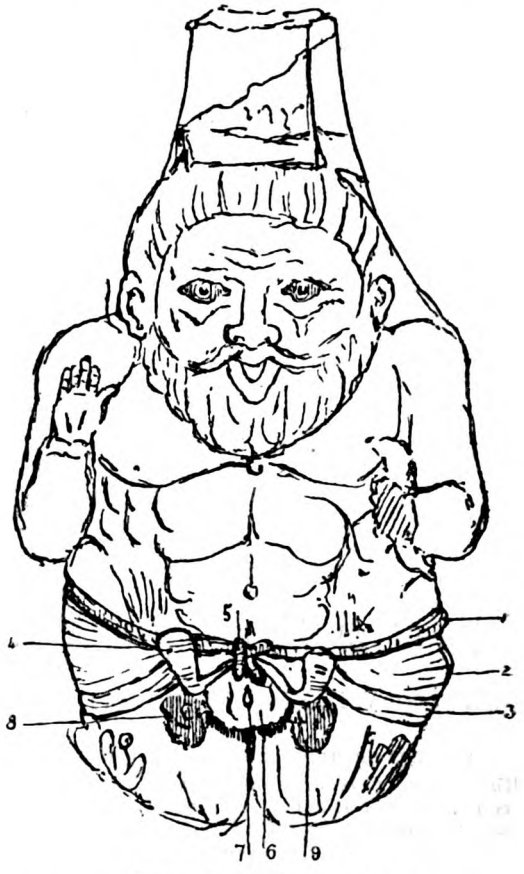
On Saturday, July 27th, the President invited the members to Broadmoor, where the wards and manner of treatment of the patients were fully described. On the following Monday the members paid a visit to the Holloway Sanatorium on the invitation of Dr. Rees Philipps, some of the members afterwards paying a visit to Windsor. Dr. and Mrs. J. Chambers gave a garden-party at the Priory, Roehampton, on Tuesday, July 30th, thus closing a very interesting and successful meeting.

HABITUAL DRUNKARDS AND THEIR RETREATS.

THE fifteenth report of the Inspector of Retreats under the Inebriates Acts of 1879 and 1880 is before us and merits the serious attention of our readers. Such legislation originated with the profession, and if it is ever to be amended and put into an adequate and effective form it will largely be on the evidence and representation of medical men. The actual report before us is satisfactory as far as it goes, or can go, but like its predecessors it only suffices to show that we have touched the mere fringe of the subject and that our legislators have yet to accomplish anything worthy of the name of legislation for the recovery of persistent drunkards, who often have in them the materials of most capable and genial citizens. The existence of such persons is only too palpable, and yet there are greater numbers than would appear to the cursory observer. It is a lucky family that cannot count within its blood relationship an incorrigible and persistent drunkard who destroys his own health, loses his employment, and squanders the property which has been acquired, sometimes by his own industry and more often by that of his relatives, possibly his parents, and sometimes his wife. The reports of a scientific or even a rough investigation by competent persons into the habits of persistent drunkards would astonish the public and remove what little reluctance may still remain to deal effectively with them. Not only the number of such persons, but their prodigious powers of consumption, would surprise the uninitiated. A bottle of brandy a day or as much whisky, or two, or even, as in one case, four, may be consumed or procured for consumption, and such a system, with more or less interruption, may go on for years without let or hindrance from legislation, though, of course, it is as distinctly poisonous and suicidal in its effect as overdoses of arsenic or of phosphorus.

The contribution of our legislators to the correction of this evil so far consists in the Acts regulating retreats and the admission of patients into them. The feature of this legislation is that if habitual drunkards consent to their own treatment in these institutions before two magistrates they can be detained for a period not exceeding twelve months. There are nine such retreats, a new one having been licensed last year—Capel Lodge, licensed to Dr. Edward Norton for eight male patients, and situated between Folkestone and Dover. The others are situated at Chiswick, Folkestone, Fallowfield (Manchester), Kingswood Park, Dalrymple Home, Rickmansworth, and Westgate-on-Sea. Early in the present year Amesbury House, Amesbury, was licensed to Mr. J. J. Bancroft for the reception of three patients, two male and one female. In the nine retreats in the year 1894 the admissions during the year were 133, 4 more than in the previous year. With 87 remaining over from the previous year this makes a total of 220. Only one death occurred in the institutions from pericarditis—that of a woman shortly after her admission. The report of the inspector consists almost entirely of the reports sent to him by the licensees of the retreats. It is disappointing not to have some independent criticism by the inspector of the retreats himself. But this is conspicuous by its absence. The details given by the licensees are very much to the same effect as in previous years and go to show that the principle of these retreats is a sound one, and is really curative in a large proportion of the cases, the principle consisting in the detention of the patient for a considerable time—twelve months if possible—under conditions in which immediate and continuous abstention from alcohol is practicable, accompanied with other conditions of a regular and cheerful life. One of the most interesting reports is that of the licensee of Fallowfield, Manchester, an institution meant for women. The testimony here is explicit on two important points. The first is that habitual drunkenness in women is by no means a hopeless disease, as it is apt to be considered. It is reported that 25 per cent. of the cases give evidence of permanent recovery. When it is considered that the patients do not go into the retreat till, for the most part, they are in an advanced and otherwise hopeless stage of alcoholism, the proportion is a very creditable one. Four women who left in 1891 (the first year) still remain steadfast abstainers and are doing well in their several stations of life. Six who left in 1892 have stood firm, and nine who left in 1893. The other point testified to in this report is that no harm, but good, is done by the sudden and complete disuse of alcohol in such cases. The report of the Dalrymple Home is, as usual, one of the most instructive of the series. Since the opening 377 cases have been discharged, of which 177 have been under the Act and 200 private cases. The accommodation is far short of the demand, so that for every applicant admitted ten or fifteen have been refused either for want of accommodation in the retreat or of means in the patient. The occupation of patients is given. It is no matter for surprise that "gentlemen of no occupation" supply the largest number of the cases—85 out of 377. Merchants seem to supply the next largest number (41); clerks, 39; medical practitioners, 28, and medical students, 5; solicitors, 18. It is important to notice that in a large proportion of cases some other habit affecting the nervous system is associated with that of alcoholism. In 321 it was the use of tobacco, in 4 chloral and tobacco, in 4 morphia, in 2 morphia and cocaine, in 6 opium or chlorodyne and tobacco, and in 1 sulphonal. In 39 there was no other associated habit. It is gratifying to notice that in this retreat reports are received from old patients (number not stated) who after periods of from seven to ten years continue to be abstainers. The Kingswood Park report states that 42 per cent. of the patients discharged are doing well. The period for which these successful cases were detained lasted from six to twelve months, and their average age was forty-one years.

The unanimous burden of the reports is that there is



Digitized by Google

need of more retreats, especially for the poor, and that little more good can be expected from the retreat system until an amendment of the law, applying the compulsory principle to persistent drunkards, is procured. On this subject the medical profession is unanimous. A Bill is already being promoted on these lines in Vienna, and our readers will remember that a similar Bill passed a second reading in the House of Lords before the recent change of Ministry, and in spite of somewhat strong speeches against it by the present Lord Chancellor and Lord Salisbury. These statesmen are now in positions of great power and can indefinitely defer the much-needed legislation in the name of personal freedom. We do not doubt that they will see that this is no question of party politics, but one concerned with disease and urgent at that. Their opposition was directed against the methods of procuring the detention of persons rather than against the principle itself. They will have public and professional concurrence in any means for protecting the just liberty of the subject, but this can scarcely imply a right to the habitual use of such quantities of alcohol as are inconsistent with the safety of a man's family or the retention of his health or of his property. The very fact that we love freedom beyond other nations should make us the more anxious not to desecrate the word by applying it to the most enslaving of vices.

A PREHISTORIC TRUSS.

DR. F. PONCET, late Principal Medical Officer of the French army in Tunis, is the fortunate possessor of a very remarkable statuette or votive image, which was recently found at Soussa, and has made it the subject of an illustrated descriptive article in our contemporary *Le Progrès Médical* of June 1st, 1895, from which we condense the following particulars. The figure, which is composed of terra cotta, measures about four inches in height by two and a half in width, and has been pronounced by M. Maspero and other Egyptologists to be an example of the Egyptian deity Bès or Bizou, whose effigies are so common on the banks of the Nile. It was found by a gentleman named Gouvet while exploring the confines of an ancient Phœnician cemetery, and is supposed to date back to about the year 900 B.C. Not only is this treasure-trove admirable as a work of art and wonderful as a relic of antiquity, it is likewise extremely interesting and valuable from a surgical point of view on account of the accurate representation it affords of two varieties of hernia—the femoral and the scrotal—as well as of a most ingenious and effective truss for use in the inguinal form of the disorder. In spite of the fact that rupture is a very common affection, being present, according to Malgaigne, in about 3½ per cent. of the entire population, there is little if anything known regarding the employment of trusses or other kindred appliances in ancient times, when, owing to the universal predilection in favour of active exercise, the incidence of the complaint must have been at least as frequent as it is at the present day. Celsus, it is true, does mention a kind of bandage for the retention of infantile hernia, and Constantine the African, who flourished at Carthage about A.D. 1100, is said to have made use of metallic instruments for adults; but with these exceptions the records of the past are completely silent on the subject. It has, nevertheless, now become evident from Dr. Poncet's manikin that the physicians of prehistoric times were quite conversant with rupture in most of its forms, and were able to palliate it by means of suitable mechanical contrivances.

As a general rule Bizou is represented as a squat figure, enormously muscular, with a gigantic head and a protruding tongue; his clothing consisting of a panther-skin cloak, fastened in front by the paws, and a cincture composed of two serpents. In the Soussa image, however, the snaky girdle gives place to a most skilfully-fashioned truss consisting of a couple of belts connected to each other by a pliable fascia, and encircling the figure above and below the great trochanters which serve to keep the entire apparatus in position. The belts are clasped at the back and do not run horizontally, but are both more or less curved, especially the lower, which forms an arch in front until it meets the other just above the pubes. Attached to the upper belt, which is evidently intended to be made of some rigid material, are two V-shaped plugs covering the inguinal canals on either side, with their broadened limbs, and then bending upwards to be joined to each other by means of a knotted tape. The great advantages connected with this apparatus are the ability to dispense with a perineal band, and the power possessed by the wearer of tightening or slackening the belts according to the condition of his abdomen. The chief disadvantages are its cumbersomeness and the difficulty that would be experienced by stout persons in adjusting it. Altogether the little figure is a perfect museum of hernial pathology; for, besides the inguinal bandage, it exhibits two multilobar crural ruptures escaping through the orifices of the cribriform fascia, and an enormous scrotal tumour wherein the penis is completely engulfed, with nothing visible but the meatus urinarius, just as, according to Sir Astley Cooper, was the case with the historian Gibbon.

SKETCH OF THE STATUETTE.[1]

1. Upper belt. 2. Material, intermediary fascia. 3. Lower belt. 4. Oblique metallic knob, terminating in a stem forming an arch. 5. Bow-knot. 6. Scrotum. 7. Urethral orifice. 8 and 9. Crural herniæ.

VACCINATION PROSECUTIONS AND THE REPORT OF THE ROYAL COMMISSION ON VACCINATION.

SOME few years ago, when the Report of the Royal Commission on Vaccination was expected to be issued in a few months, the Wigan board of guardians agreed not to institute proceedings against defaulters till the report was received. Since then vaccination in the borough of Wigan has been practically in abeyance, much to the gratification of anti-vaccinationists. Now

[1] We are indebted to the Editor of *Le Progrès Médical* for permission to reproduce this sketch.

Digitized by Google

the town is suffering from a smart epidemic of small-pox, and although there have been only one or two deaths there have been upwards of sixty cases since the first attack on May 22nd last. The sanitary officers are doing their best to cope with the outbreak, yet no notices are placarded or additional facilities made for revaccination, and the only preventive (vaccination) is not enforced. The guardians, however, seem to have awakened from their lethargy and by a resolution of the board on Aug. 23rd gave instructions to Mr. Halliwell, the vaccination officer, to take proceedings against defaulters of children registered between Jan. 1st and March 31st last. Some 150 summons were issued a fortnight since, and this threw consternation in the ranks of the anti-vaccinationists, who at once held meetings and decided to defend the cases, which were adjourned. In the meantime they held a public meeting, when the usual stock arguments were forthcoming, and the usual intemperate language against the authorities was employed, although the cases were still *sub judice*. The cases were tried last week, and at the commencement of the proceedings Mr. Duxbury said that a fortnight ago, when the cases were adjourned, a suggestion was made that the consideration of the whole question should be left in abeyance until they had received the report of the Royal Commission, which had been sitting for six or seven years. He said they had every reasonable anticipation of receiving this report in the next few months. The chairman (Mr. Marshall) said they had been waiting six years for the report. The cases were then heard; some were dismissed, but the majority were fined 1*s.* and costs. The ratepayers are complaining bitterly of their heavy rates and of the cost of maintaining their excellent sanatorium for infectious diseases. Even this little epidemic will cost something and add to its maintenance account, whereas if vaccination had been proceeded with as heretofore the epidemic would probably have been limited, because the origin of the epidemic was due to a person who lived a nomadic life.

Public Health and Poor Law.

LOCAL GOVERNMENT DEPARTMENT.

REPORTS OF MEDICAL OFFICERS OF HEALTH.

Warwickshire County Sanitary District.—For the last six years Dr. Bostock Hill has presented to the Warwickshire County Council a summary of the annual reports of the district medical officers of health, and that for 1894 is now before us. The estimated population of the administrative county is 317,952, and during 1894 there has been a decided increase in the urban districts as against a decrease in the rural. The death-rate in the rural districts was—as in 1893—higher than in the urban districts, a peculiarity explained by the urban nature of the rural districts. The general death-rate of the county was but 14·07 per 1000, the lowest recorded since the presentation of Dr. Hill's reports. The death-rate of the county was from typhoid fever 0·05, from diphtheria 0·08, and from scarlet fever 0·05 per 1000 of the population, all of which rates were below the average for the last six years. The "infantile" mortality rate was also the lowest recorded during the same period, and some of the low rates indicate, Dr. Hill thinks, that slowly, but surely, a better knowledge is being brought to bear as to the requirements of early infant life. Two urban and one rural districts are still recalcitrant in the matter of notification. Dr. Hill regrets that very little information is given in the district reports as to the condition of vaccination, and he is evidently in favour of vaccination being in the hands of sanitary authorities. The weekly return of infectious disease made by the Warrington County Council seem to be much appreciated in the county, and the city of Coventry has applied to be furnished with copies. The County Council should, Dr. Hill remarks, approach the Corporation of Birmingham with a view of exchanging notification returns with them. The fact of Birmingham possessing a population nearly twice as great as that of the rest of the county renders it, he observes, of great importance to ascertain the origin and spread of infection in that city.

Bolton Urban Sanitary District.—The general death-rate of Bolton (population 118,303) for 1894 was 18·7 per 1000, as against 23·9 for 1893, and Dr. Frederick Adams furnishes in his report a table showing the death-rate of the district per 1000 of the population since the year 1851. The gradually diminishing rate shown from decade to decade should certainly be a great encouragement to the sanitary authority of Bolton to proceed with reform. The rates for the four decades comprised between 1851-90 were as follows:—30·7, 27·5, 23·8, and 21·8, while the rate for the four years 1891-4 was 21·7.

South Shields Urban Sanitary Authority.—Dr. W. H. Turnbull in his annual report for 1894 draws the attention of the sanitary authority to the fact that there are over 120 seamen's lodging-houses in South Shields, and he points out that the staff of the health department available for the systematic inspection of these premises, consisting as it does of only two inspectors, is quite inadequate. Dr. Turnbull observes that it is somewhat remarkable that although the population of the borough has nearly doubled itself during the last twenty years and increased enormously in commercial prosperity, the sanitary staff should have remained practically *in statu quo*. Dr. Turnbull considers that in South Shields there should be one inspector to every 10,000 of the population.

VITAL STATISTICS.

HEALTH OF ENGLISH TOWNS.

IN thirty-three of the largest English towns 6273 births and 4269 deaths were registered during the week ending Sept. 28th. The annual rate of mortality in these towns, which had been 19·3 and 19·8 per 1000 in the two preceding weeks, further rose last week to 21·0. In London the rate was 18·2 per 1000, while it averaged 23·0 in the thirty-two provincial towns. The lowest rates in these towns were 14·7 in Huddersfield, 15·0 in Croydon, 16·1 in Leicester and in Portsmouth, and 16·5 in Bristol; the highest rates were 29·4 in Blackburn, 29·5 in Sunderland, 29·7 in Bolton, 29·9 in Manchester, and 30·5 in Gateshead. The 4269 deaths included 923 which referred to the principal zymotic diseases, against 990 and 981 in the two preceding weeks; of these, 604 resulted from diarrhœa, 81 from diphtheria, 69 from whooping-cough, 60 from measles, 57 from "fever" (principally enteric), 50 from scarlet fever, and 2 from small-pox. The lowest death-rates from these diseases were recorded in Croydon, Plymouth, Norwich, Derby, and Halifax; and the highest rates in Bolton, Burnley, Blackburn, Hull, Sunderland, and Gateshead. The greatest mortality from measles occurred in West Ham and Blackburn; from scarlet fever in Huddersfield; from whooping-cough in Gateshead, Wolverhampton, Bradford, and Bolton; from "fever" in Bolton and Sunderland; and from diarrhœa in Cardiff, Nottingham, Burnley, Bolton, Blackburn, and Hull. The 81 deaths from diphtheria included 56 in London, 8 in West Ham, and 3 in Birmingham. Two fatal cases of small-pox were registered in London, but not one in any other of the thirty-three large towns. There were 234 cases of small-pox under treatment in the Metropolitan Asylum Hospitals and in the Highgate Small-pox Hospital on Saturday last, Sept. 28th, against 328, 307, and 271 at the end of the three preceding weeks; 21 new cases were admitted during the week, against 25, 42, and 23 in the three preceding weeks. The number of scarlet fever patients in the Metropolitan Asylum Hospitals and in the London Fever Hospital at the end of the week was 2087, against 2600, 2674, and 2732 on the three preceding Saturdays; 339 new cases were admitted during the week, against 336, 365, and 344 in the three preceding weeks. The deaths referred to diseases of the respiratory organs in London, which had been 123 and 141 in the two preceding weeks, further rose to 173 last week, but were 37 below the corrected average. The causes of 54, or 1·2 per cent., of the deaths in the thirty-three towns were not certified either by a registered medical practitioner or by a coroner. All the causes of death were duly certified in Portsmouth, Leicester, Nottingham, Oldham, Newcastle-upon-Tyne, and in nine other smaller towns; the largest proportions of uncertified deaths were registered in Cardiff, Wolverhampton, Preston, and Hull.

HEALTH OF SCOTCH TOWNS.

The annual rate of mortality in the eight Scotch towns, which had been 16·9 and 19·5 per 1000 in the two preceding weeks, declined again to 17·5 during the week ending

Digitized by Google

Sept. 28th, and was 3·5 per 1000 below the mean rate during the same period in the thirty-three large English towns. The rates in the eight Scotch towns ranged from 13·2 in Aberdeen and 13·5 in Leith to 19·4 in Glasgow and 20·5 in Dundee. The 506 deaths in these towns included 48 which were referred to diarrhœa, 9 to whooping-cough, 6 to measles, 6 to "fever," 5 to diphtheria, 5 to scarlet fever, and not one to small-pox. In all, 79 deaths resulted from these principal zymotic diseases, against 90 and 93 in the two preceding weeks. These 79 deaths were equal to an annual rate of 2·7 per 1000, which was 1·8 per 1000 below the mean rate last week from the same diseases in the thirty-three large English towns. The fatal cases of diarrhœa, which had declined in the four preceding weeks from 78 to 57, further fell to 48 last week, of which 19 occurred in Glasgow, 10 in Dundee, and 6 in Edinburgh. The 9 deaths from whooping-cough were within one of the number in the preceding week, and included 2 each in Glasgow, Dundee, Leith, and Greenock. The deaths referred to different forms of "fever," which had increased from 4 to 16 in the three preceding weeks, declined to 6 last week, of which 4 occurred in Glasgow. The 5 fatal cases of scarlet fever slightly exceeded the numbers recorded in recent weeks, and included 3 in Glasgow. The deaths from diphtheria, which had been 5 and 3 in the two preceding weeks, rose again to 5 last week, of which 3 occurred in Edinburgh. The deaths referred to diseases of the respiratory organs in London, which had been 52 and 66 in the two preceding weeks, further rose to 82 last week, and exceeded by 14 the number in the corresponding week of last year. The causes of 28, or nearly 6 per cent., of the deaths in these eight towns last week were not certified.

HEALTH OF DUBLIN.

The death-rate in Dublin, which had been 25·4 and 22·1 per 1000 in the two preceding weeks, rose again to 24·8 during the week ending Sept. 28th. During the thirteen weeks of the quarter ending on Saturday last the death-rate in the city averaged 23·4 per 1000, the rate during the same period being 18·6 in London and 16·5 in Edinburgh. The 166 deaths registered in Dublin during the week under notice showed an increase of 18 upon the number in the preceding week, and included 24 which were referred to the principal zymotic diseases, against 21 in each of the two preceding weeks; of these, 13 resulted from diarrhœa, 4 from whooping-cough, 2 from small-pox, 2 from scarlet fever, 2 from "fever," 1 from measles, and not one from diphtheria. These 24 deaths were equal to an annual rate of 3·6 per 1000, the zymotic death-rate during the same period being 3·0 in London and 2·1 in Edinburgh. The fatal cases of diarrhœa, which had been 12 in each of the two preceding weeks, were 13 last week. The 4 deaths referred to whooping-cough exceeded the number in any recent week. The fatal cases of "fever," which had been 4 and 5 in the two preceding weeks, declined to 2 last week. The 2 fatal cases of scarlet fever corresponded with the number in the previous week. The 166 deaths in Dublin last week included 42 of infants under one year of age, and 35 of persons aged upwards of sixty years; the deaths both of infants and of elderly persons considerably exceeded those recorded in the preceding week. Two inquest cases and 4 deaths from violence were registered; and 48, or nearly a fourth, of the deaths occurred in public institutions. The causes of 15, or nearly 9 per cent., of the deaths in the city last week were not certified.

THE SERVICES.

MOVEMENTS OF THE MEDICAL STAFF.

BRIGADE-SURGEON-LIEUTENANT-COLONEL MACNAMARA, lately commanding the Depôt, Medical Staff Corps at Aldershot, has embarked for a tour of service in Egypt, and Surgeon-Lieutenant-Colonel Allin will succeed him. Surgeon-Captain Kennedy has embarked for Egypt.

INDIA AND THE INDIAN MEDICAL SERVICES.

Surgeon-Major J. Maitland. M.D., is appointed to act as Senior Medical Officer, General Hospital, Madras, during the absence of Brigade-Surgeon-Lieutenant-Colonel W. Price, M.D., on leave. Surgeon-Major J. Smyth, M.D., is appointed to act as Surgeon, General Hospital, Madras, during the employment of Surgeon-Major J. Maitland on other duty. Surgeon-Major M. O'Dwyer, Civil Surgeon, is appointed to officiate as deputy Sanitary Commissioner, Punjab, as a temporary arrangement, vice Surgeon-Captain H. J. Dyson, whose services have been placed at the disposal of the Government of India. Surgeon-Captain R. Bird, Resident Surgeon, Medical College Hospital, is appointed to act as Professor of Anatomy, Medical College, Calcutta, in addition to his own duties, until further orders. The undermentioned officers retire from the service:—Surgeon-Lieutenant-Colonel J. A. Laing, Madras Establishment; Surgeon-Lieutenant-Colonel E. B. Ruttledge, Bengal Establishment, Civil Surgeon, North-West Provinces and Oudh.

NAVAL MEDICAL SERVICE.

The following appointments are notified:—Staff-Surgeons: John Hunter to the *Edgar*, and A. W. May to the *Benbow*.

ARMY MEDICAL RESERVE OF OFFICERS.

Surgeon-Captain Richard C. M. Pooley, having resigned his Volunteer appointment, ceases to be an Officer of the Army Medical Reserve of Officers. Surgeon-Lieutenant Henry D. Brook to be Surgeon-Captain. Surgeon-Lieutenant Hamilton Chambers Reid, M.B., Glasgow Companies Volunteer Medical Staff Corps, to be Surgeon-Lieutenant.

VOLUNTEER CORPS.

Royal Engineers: 2nd West Riding of Yorkshire (Leeds): The services of Surgeon-Lieutenant C. Malcolm are dispensed with. 3rd Volunteer Battalion the Manchester Regiment: Surgeon-Lieutenant J. W. Talent, M.B., resigns his commission.

THE MADAGASCAR CAMPAIGN.

The latest intelligence from Madagascar is somewhat better. The general commanding telegraphed to the French War Office from Andriba on the 27th ult. that the Voyron detachment had crossed the Ankaraka Mountains and had been joined by General Metzinger's detachment and were marching against Babay. The Hovas have so far offered little or no resistance, and the health and spirits of the troops composing the advancing French force are reported to be excellent. It is expected, however, that the Hovas will offer some opposition to the French at Babay, which is only about thirty kilometres from Antananarivo. The flying column amounts to an effective total of 5000 men with twenty-two days' supplies. So far for the force in the uplands; but there is no further intelligence regarding the troops on the seaboard in the lowlands. There will probably be a good deal of sickness and inefficiency among the troops in the field during the rainy season, and it is important that Antananarivo should soon be reached. General Zurlinden reports that since the arrival in France of the first batch of sick troops from Madagascar there have only been nine deaths, and that since the arrival of the *Concordia* there have been none. There are 400 invalids from Madagascar in hospital at Marseilles, but only three of them are in a critical condition. General Zurlinden, the French Minister of War, paid a long visit to the military hospital at Marseilles on the 30th ult. and made many inquiries of the patients as to their state of health and their impressions about Madagascar and the campaign. Pitiable accounts are given by the French soldiers and marines who have just arrived at Marseilles in the mail steamer *Australien* of the sanitary condition of the troops in Madagascar. It is the old story of want of preparation and foresight, defective transport and supplies, overworked and overweighted troops, and inadequate hospital accommodation with insufficient medical and nursing staff.

DEATHS IN THE SERVICES.

Surgeon-General Sir Thomas Longmore, C.B. (retired), at Swanage, on Tuesday last, in his seventy-ninth year. He was educated at Guy's Hospital, became Surgeon in the Army in 1854, Deputy-Inspector-General in 1858, and Inspector-General in 1872. He served throughout the Crimean campaign in 1854–55, and in Bengal during the Sepoy Mutiny. He was Professor of Military Surgery at the Army Medical School, Netley, from 1860 to 1891. He held the appointment of honorary surgeon to the Queen and was a Knight of the Legion of Honour.

Surgeon-General Hampden Hugh Massy, C.B. (retired), at his residence, Bournemouth, on the 27th ult., aged seventy-five. The late officer had seen a great deal of service in the Crimea, was head of the sanitary branch of the medical department under Sir Galbraith Logan, became Deputy-Surgeon-General at Bangalore, Madras, and subsequently Principal Medical Officer at Netley.

M. HAFFKINE.

We are very sorry to learn that M. Haffkine is compelled to leave India owing to impaired health, attributable to the effects of an attack of climatic fever contracted in Assam. By his exhibition of self-sacrifice and enthusiasm in prosecuting the work he had undertaken in India M. Haffkine is well entitled to the esteem in which he is evidently held in that country. He has been indefatigable in his labours, has spent a large sum of money, and has sacrificed his time, and now his health, in the cause he had at heart. We sincerely join with his many friends in wishing him a speedy restoration to health.

MEDICAL REFORM IN INDIA.

We learn from the Anglo-Indian papers that a movement has been started among the native medical element in Bombay for the separation of the civil and military medical services, with reconstitution of the civil branch and the advancement and recognition of its subordinate grades. A committee has been formed for the purpose, and a preliminary meeting held for settling the outlines of a programme of medical reform in India, and for the organisation of local committees at different centres in India and the formation of a fund are contemplated.

TYPHOID FEVER AT POONA.

There has been a considerable amount of enteric fever at Poona of late, and some fatal cases have occurred among the officers at that station.

The Surgeon-Major-Generalship at Gibraltar has been transferred to Devonport, and the medical charge at Gibraltar will be held by a Surgeon-Colonel.

"Audi alteram partem."

"MERCURY IN HEART DISEASE."

To the Editors of THE LANCET.

SIRS,—I have been much interested in reading Dr. W. Murray's article under the above heading in THE LANCET of Sept. 28th. I concur fully in his opinion of its great value in all cases of heart disease where passive congestion and œdema are present. I well remember a remark of Dr. Stone, at St. Thomas's Hospital, concerning the value of the well-known pill containing equal parts of squill, digitalis, and blue pill. "Both Dr. Murchison and I," said he, "highly appreciate this prescription. But he will only allow any potency to the digitalis there is in it and forgets all about the blue pill, whereas I, perhaps, am liable to think too little of the digitalis and place all my trust in the mercury." My own experience leads me also to think far more highly of mercury (or calomel) in the treatment of passive cardiac congestion than of digitalis. Dr. Murray believes it has a peculiar tonic action on the heart itself. Though not denying such action, I do not see that it is necessary to explain the efficacy of the drug in these cases. Water-logged tissues can only exhibit a feeble vitality. The water-logged lungs, liver, kidneys, pancreas, intestinal and lymphatic glands can, therefore, but feebly perform their nutritive functions. Food will thus be imperfectly assimilated and effete material imperfectly removed. The circulation of the resulting poisonous matters in the body will still further paralyse all its functions, including that of the already weak heart, and, what is of still greater importance in this respect, nature's endeavour to prevent the circulation of these poisons, by constricting the peripheral arterioles, will double and treble the heart's labour. Common-sense reasoning would urge us not to drive the heart, but rather to relieve it of all unnecessary labour. This is what mercury does by its unique power of stimulating all glandular organs. It urges them to healthy metabolism, notwithstanding their œdematous condition. Hence the ptomaines vanish and with them the constriction of the arterioles, freeing the heart of half its labour. It is thus I would explain the excellent action of mercury in the case so well detailed by Dr. Murray, and also in one I have recorded on page 389 of "Essays in Heart and Lung Disease," which is briefly this: "A man with double aortic disease had orthopnœa and ascites, as well as general œdema. He was given cardiac tonics for three days with no relief, the urine remaining at twenty ounces. I then gave him a third of a grain of calomel every two hours; the urine at once rose to over 100 ounces, and in ten days the œdema and orthopnœa were quite gone, the heart was calm, and the pulse, which had been small and hard, was large and duly soft."

I am, Sirs, yours truly,

Birmingham, Sept. 28th, 1895. ARTHUR FOXWELL.

"OVER-OPERATING IN GYNÆCOLOGY."

To the Editors of THE LANCET.

SIRS,—Mr. Lawson Tait, in his letter in THE LANCET of Sept. 21st, speaks of the "bagatelle risk of 1·6 per cent. mortality." Does he remember the mortality of about 15 per cent. in an institution in this town for the establishment of which he is responsible? Mr. Tait writes as though abdominal sections were resorted to chiefly for the removal of pus. It has been observed here by myself and others that ovaries and tubes said to be diseased have after removal proved to be not only free from pus, but from any sign of disease sufficient to justify the operation.

I am, Sirs, yours faithfully,

Southampton, Sept. 28th, 1895. J. F. BULLAR.

"A RARE FORM OF SKIN DISEASE FOLLOWING THE EXTERNAL APPLICATION OF IODINE LINIMENT."

To the Editors of THE LANCET.

SIRS,—Perhaps you will permit me to draw attention to a few points in connexion with Dr. Dobie's interesting case published in THE LANCET of Sept. 28th. In 1890 I pointed out that many drugs and specific poisons had the power, when introduced into the system, of irritating any or all of the channels of excretion. In this way we get dermatitis, bronchitis, dyspepsia, diarrhœa, nephritis, and so on in connexion with gout, ptomaines, exanthems (such as scarlet fever), and various drugs. Iodine is one of the drugs that seems to be capable of inflaming any of the excretory outlets. Its excretion, when not carried out by the kidneys, gives rise to the interesting group of symptoms known as "iodism." It has, moreover, actually been detected in the pustules of some forms of iodine rash. For some years I have been on the look-out for iodism where there was distinct evidence of kidney inadequacy. In Dr. Dobie's case there were albuminuria and signs of advanced kidney disease. My suggestion is that the iodine was absorbed into the circulation by the skin, that it was not excreted by the usual channel, the kidney, and that the severe general subsequent dermatitis was due to an attempt of the skin to throw off the irritant iodine; that the rash was, in fact, caused by excretory irritation.

I am, Sirs, yours faithfully,

Pump-court, Temple, E.C., Sept. 28th, 1895. DAVID WALSH.

"THE FIFTH YEAR OF MEDICAL STUDY AND PUPILAGE."

To the Editors of THE LANCET.

SIRS,—With regard to devoting six months of the last year of pupilage in the practice of a general practitioner, alluded to in your most interesting leading article in THE LANCET of Sept. 28th, is there anything to prevent the pupil, after he has qualified, returning to the scene of his last days of pupilage, taking advantage of the six months' introduction he has had to the patients of the general practitioner, and commencing a practice on his own account?

I am, Sirs, yours truly,

Park-street, Windsor, Sept. 27th, 1895. W. B. HOLDERNESS.

"HOSPITAL ABUSE AT BRIGHTON."

To the Editors of THE LANCET.

SIRS,—The committee of management of the Sussex County Hospital have noticed with much concern a paragraph in THE LANCET of Sept. 21st, founded on a letter in a local newspaper, on alleged abuse of the charity by patients able to pay for medical attendance. Such a statement in the leading medical journal, if allowed to go

Digitized by Google

unquestioned, would be more than likely to act prejudicially to the interests of the hospital, and though the committee would have welcomed the opportunity of reply previous to this publication they now hasten to lay before the Editors the following facts, which they trust may receive their attention, and should such commend itself to them induce some favourable notice in the next issue of THE LANCET. Before proceeding further the committee would point out a misleading statement in the letter above alluded to. The writer states: "The patients are drawn from a population of 150,000," though he goes on to mention: "Some of the patients are from other parts of Sussex;" as a matter of fact the Sussex County Hospital is for "the sick and lame poor of all nations," and from the figures of the first six months of the current year it is shown that 35·8 per cent. of the in-, and 21 per cent. of the out-patients were derived from places quite outside the towns of Brighton and Hove. The possibility of such abuse has from time to time received anxious considerations by the managing governors, and last year a subcommittee endeavoured in the most painstaking way to elicit the actual state of affairs in respect to this matter. The correspondent, quoted in THE LANCET, gives as an instance of abuse a supposititious case of hospital treatment of a child of a workman in receipt of 35*s.* or £2 a week, and yet there may be circumstances—to wit, a large family, other home sicknesses, operations, special treatment or nursing required, &c.—which may make the case, not only deserving of such treatment, but one that no hospital could refuse. The subcommittee, wishing to start on some definite principle, primarily laid down a scale as to what should under ordinary circumstances constitute a claim for admittance—say, a weekly income of £1 or less for single men, £1 2*s.* 6*d.* for married men, and an extra 2*s.* 6*d.* each for every child not earning a livelihood. As the circumstances, &c., of in-patients can during their residence in hospital be looked into, and their numbers are comparatively smaller, the inquiry was confined to the out-patient department. Several weeks letters of recommendation were carefully scrutinised, those not fully filled in were sent back for further particulars, and in certain cases were referred to the honorary medical officers in charge of the cases for their opinions as to the nature of the complaints and their claim for hospital treatment. In addition to this, the subcommittee took 100 letters pertaining to out-patients from Brighton and Hove, and personal inquiries were made into these through the Charity Organisation Society, clergymen of their parishes, their own houses, and other channels as to the verity of particulars given, and the justice of giving gratuitous treatment. To enter into the very many other particulars of this inquiry would extend this letter to inordinate dimensions, and the committee of management, therefore, merely quote the final result as given in their last annual report: "A searching scrutiny was made this year by a subcommittee, which showed that 96 per cent. of the cases were entirely fit and proper subjects for gratuitous treatment, and though in the remaining 4 per cent. sufficient evidence could not be obtained, it was thought that even in these cases, were closer scrutiny possible, it might be shown that several could be received without any abuse of the charity." It may here be mentioned that in the early part of 1894 an urgent appeal accompanied the annual report, urging all subscribers to exercise a closer supervision over all letters of recommendation granted by them Were this alleged abuse merely applicable to the charities quoted by the aforementioned writer of the letter, such would be of much greater weight, but it equally applies to all hospitals in the kingdom, and was prominently brought out as regards London in the inquiries made by the Lords' Committee. As regards the Sussex County Hospital, the facts herein narrated show how alive the managing governors are to check any such abuses, but the difficulty is very great, and the inquiries, both in reference to the patients themselves and the subscribers who recommend them, require delicacy and tact. Instead of dissolving the subcommittee at the end of the inquiry, it was considered that it would be politic and useful to keep it on in permanence for any further matters that might occur in reference to the same subject, and the committee can only say that if anyone will acquaint them with any case of abuse or suggest any practical remedies, such will receive their earnest attention and grateful thanks.

I am, Sirs, yours faithfully,

Brighton, Sept. 28th, 1895. W. H. ORTON, M.A., Secretary.

*** We are happy to give insertion to the above letter and are satisfied that the committee of the Sussex County Hospital are anxious to restrict the use of that institution to fit cases. We agree that even with 40*s.* wage there may be elements of sickness or misfortune in a family entitling it to consideration, but these cases are rare; and we are still of opinion that the committee will best command the respect of their supporters by keeping a very strict eye on persons abounding in every community who take as a charity that for which they should pay.—ED. L.

"RETURN" CASES OF SCARLET FEVER.

To the Editors of THE LANCET.

SIRS,—In THE LANCET of June 22nd last you published an article by Dr. A. K. Chalmers in reference to the reappearance of scarlet fever in a household shortly after the return of one of the inmates from hospital. *Apropos* of this subject the following case will be interesting. A child returned home on Aug. 31st last, after a residence of nine weeks and three days in a scarlet fever hospital. The nightgown and one or two small articles were returned to the mother, with a form stating that the said things had been properly disinfected and were free from risk of causing infection. This was on Saturday. On the Monday a sister of the patient wore the nightgown that had been returned from the hospital two days before. On the Wednesday night, forty-eight hours later, she was seized with sickness. On Thursday morning I was called to see her. On Friday morning the rash had appeared. I certified it as scarlet fever, and the child was removed to the hospital, where she died. I am not aware of any scarlet fever cases at all close by; the child that had come back was quite free from desquamation; it was holiday time, so school had nothing to do with it. There remains only the possibility of infection through the nightgown brought from the hospital. *Post hoc* is not always *propter hoc*, but in this case there is no doubt whatever in my mind that that is how the disease was produced. There can be no question that disinfection is thoroughly and efficiently carried out. Whence, then, the failure? I venture to suggest that the air in and immediately around a fever hospital is so full of germs that drying linen becomes reinfected. If so, either all articles must be destroyed, or disinfected elsewhere than at the hospital, and must be returned direct to the patients' homes without being taken again to the hospital. This is the second occasion within a few months in which the return of one of my patients from hospital has been signalised by a second outbreak in the same house. In both cases the homes and infected articles were disinfected on the removal of the first patient, and remained free from suspicion until the return of that patient. The importance of this subject justifies wide discussion.

I am, Sirs, yours faithfully,

Herne Hill, S.E., Sept. 28th, 1895. E. PAGET THURSTAN, M.D.

"THE EFFECT OF THYROID EXTRACT IN MYXŒDEMA COMPLICATED BY ANGINA PECTORIS."

To the Editors of THE LANCET.

SIRS,—May I point out regarding Dr. H. C. L. Morris's interesting note in THE LANCET of Sept. 28th on the above subject that the pathology of his patient's case is probably neither difficult nor puzzling, and that there is no need to invoke the aid of the nervous system? For many years I have been pointing out[1] that the high blood pressure which is the cause of the angina is nearly always the result of excess of uric acid in the blood. I have also pointed out[2] that extract of thyroid gland is practically equivalent to uric acid as regards both its physiological and pathological effects. Given these two points, the pathology of this case is simple enough—the uric acid or similar xanthin compounds contained in the thyroid extract entered the blood, raised the pressure, and made the angina worse. But, as Dr. Morris points out, Professor Schäfer has recently shown that thyroid extract lowers blood pressure, and it is quite true that it shares this effect with uric acid and the whole of the xanthin group. But it is also true that this primary fall of blood pressure is followed later by an equally constant and fully equivalent rise, and it is during this secondary rise of blood

[1] Uric Acid, second edition, pp. 111 and 139.
[2] Ibid., p. 74.

Digitized by Google

pressure that the angina occurs. This is probably so even in Dr. Morris's own case, as he tells us, with reference to the second attack, that he gave "two grains and a half every second day," and that "he experienced no discomfort until the twelfth day." Now, if the thyroid was given, as seems probable from the context, on the first, third, fifth, and uneven days, then there was none given on the even days, and the attack occurred on the even day, the twelfth—i.e., the dose given on the eleventh caused a fall of blood pressure on that day followed by a rise next day, and this rise was increased by a certain amount of uric acid or xanthin which had accumulated during the previous administrations from the first to the eleventh day, some fifteen grains in all. My writings on angina have been quoted by others as explaining their cases, notably by Professor T. J. Mays,[3] who also points out the very interesting fact that the attack of angina may, just like the attack of headache or epilepsy, be preceded by feelings of exaltation and well-being. In other words, there is a fluctuation in the excretion of uric acid: with its diminished presence in the blood and minus excretion in the urine go relaxed arterioles, low blood pressure, and mental brightness or well-being; with its natural and corresponding fluctuation in the opposite direction there is excess of uric acid in the blood and urine, and with that go contracted arterioles, high blood pressure, and the headache, the fit, or the angina. The parallel between these diseases is therefore absolute and depends on community of causation; neither of them is directly due to the nervous system, but only to the effects of the altered circulation upon it. I have heard of at least one case of epilepsy in which the administration of thyroid extract for some other trouble seemed to increase the fits or bring them on when otherwise absent, and I can answer for it that it has the same effect in headache. I also hope to publish shortly a case of epilepsy in which it rather appears that by controlling the daily introduction of uric acid I was able to control to some extent the frequency of the fits.

I am, Sirs, yours faithfully,

Brook-street, W., Sept. 30th, 1895. ALEXANDER HAIG.

"HOW SCARLET FEVER IS SPREAD."

To the Editors of THE LANCET.

SIRS,—I am obliged for your annotation in THE LANCET of Sept. 28th under the above heading relating to a case of mine in the Lexden and Winstree district, which you have described very fairly, but not so strongly as the case really stood. The family in question had been ill for weeks at Coggeshall, and after some of them had recovered—and, I may say, all were convalescent—they were removed to a lodging-house at West Mersea, which was not away from other houses of the like character, as the medical attendant told me in his letter he understood to be the case, but right in the middle of the village and between two such houses. This removal occurred on Aug. 14th, and on the morning of the 20th I had a letter from the medical attendant enclosing five notifications, each of which related to a member of this family. Each certificate stated that the individual "is suffering from scarlet fever." Our case was exposure on the public road and the beach between these dates. One would have thought the offence was very clearly put before the magistrates, yet the majority decided to dismiss the case. It is hard enough to have to take the trouble to get such cases up, which one simply does for the public safety, and I can assure you the work entailed is far from being inconsiderable; but it is most annoying to get beaten in such a straight-running case and then to be jeered at by the father of the family when you meet him in the street. I send you a copy of the *Clacton News*, giving a report of a case prosecuted at Thorpe bench last Monday for the conveyance of a girl suffering from diphtheria by rail and carrier's van from Clacton-on-Sea to Sibton Street in Suffolk. This case had a very different ending, a fine of £3 having been inflicted, although on account of the woman's poverty the costs were remitted by the magistrates. It is high time that such ignorant and obstinate individuals were shown that they must obey the law, and not break it as it suits them at the time. I serve three most painstaking authorities, and I feel sure either of them would be ready to enter a prosecution in any case where the public safety was endangered.

I remain, Sirs, yours faithfully,

Colchester, Sept. 30th, 1895. JOHN W. COOK, M.D. ABERD.

"PRESYSTOLIC APEX MURMUR WITHOUT MITRAL STENOSIS."

To the Editors of THE LANCET.

SIRS,—Dr. Phear's interesting paper having raised in the columns of THE LANCET the question of the nature of presystolic murmurs, I am induced to lay before you a view of the question which has not yet, I believe, received attention. From the observations of Dr. Phear and others, it is quite clear that constriction of the mitral orifice is not an essential element in the production of such murmurs; nor is this surprising, for it is well made out that a very slight irregularity in the blood passages will give rise to these phenomena. I believe we can go a step further. It is an established fact that some kinds of irregularities in the flow of the blood (dependent, no doubt, upon irregular action of the propelling mechanism), without any definite or at least permanent change in the blood passages, are capable of causing murmurs—the so-called hæmic murmurs. These are usually coincident with the ventricular systole, but there is no reason why such murmurs should not be produced wherever there is a flow of blood. Now there is such a flow into the ventricle during ventricular diastole, and a pretty sharp one too. The *bruit de diable*, resembling the presystolic murmur in its rumbling character, is produced by the mere venous flow of blood. Two cases that have come under my notice lately have led me to believe that hæmic presystolic murmurs do occur. In both of these a pure presystolic murmur was noticed on admission to the out-patients' department of the Victoria-park Chest Hospital, but could not be demonstrated a few weeks afterwards. The patients were not anæmic and no thrill was felt. I am inclined to think that, if those presystolic murmurs which are not accompanied by much distress were followed up, some, though perhaps not a very large percentage, of them would be found to disappear, and should be rightly placed in the category of hæmic murmurs.

I am, Sirs, yours faithfully,

London, Oct. 1st, 1895. T. GLOVER LYON.

PREMATURE INTERMENT.

To the Editors of THE LANCET.

SIRS,—It is worthy of remark, in connexion with a question which is at present exciting some discussion, that a greater prominence has not been given to the loss of electro-muscular excitability as a sign of death. Forty years ago the subject was investigated by Crimotel, twenty years later by Rosenthal, and more recently by Onimus. It seems safe to say that in no disease, certainly in none of those conditions usually enumerated as likely to be mistaken for death, is galvanic and faradaic excitability abolished in every muscle of the body. On the other hand, electro-muscular contractility disappears in all the muscles within a few hours after death (generally ninety minutes to three hours according to Rosenthal), its persistence varying to some extent with the particular muscle examined,[1] and with the mode of death[2]. Therefore, if electro-muscular contractility be present in any muscle it means life or death only a few hours before. It is clear that no interment or post-mortem examination ought to take place so long as there is any flicker of electric excitability. To me it seems almost equally obvious that in all doubtful cases, sometimes in sudden death and often to allay the anxiety of friends, this test ought to be applied, and applied by one who is accustomed to handle electric currents for purposes of diagnosis.

I am, Sirs, yours faithfully,

Brighton, Oct. 1st, 1895. W. S. HEDLEY.

"DEATH FROM VEGETABLE POISONING."

To the Editors of THE LANCET.

SIRS,—Your Manchester correspondent declares that "any apparent scepticism was not as to the symptoms, for

[1] Onimus, experimenting on a guillotined criminal, found that two and a half hours after death electro-muscular contractility disappeared in the tongue, diaphragm, and muscles of the face. In the limbs the extensors died before the flexors. The muscles of the back were contractile up to five or six hours after death and the abdominal muscles longer still. Beard and Rockwell, eighth edition, p. 152.

[2] Disappears more rapidly after death from chronic than from acute disease; more rapidly in wasted than in well-nourished muscles.—Rosenthal.

Digitized by Google

they were not described in the report." Here he is right, but the scepticism, which was real as well as apparent, referred to the want of a description of the symptoms; and to the great majority of persons of ordinary education this, together with the whole tenor of the article, conveys the innuendo that there were no symptoms to describe or that they would not bear out the conclusion come to. Your correspondent admits "apparent scepticism" firstly as to the occurrence of henbane in the park. I beg to meet this and to answer the last sentence in the article of last week by saying that henbane does grow in the park. The second cause of "apparent scepticism" being founded on an error—viz., that the deceased said she ate green sauce (she did not say this)—therefore falls to the ground.

I am, Sirs, your obedient servant,

Gorton, Manchester, Sept. 30th, 1895. B. W. MACARTHUR.

THE INTERNATIONAL CONGRESS OF HYGIENE AND DEMOGRAPHY, BUDAPEST, 1894.

To the Editors of THE LANCET.

SIRS,—I take the liberty of asking you kindly to grant space in your valuable paper for the following statements. We are now sending out to the members of the Congress the first volume of the Transactions of the Congress. Members who have not previously sent in their addresses, or who may have since changed their domicile, are respectfully requested to send in correct addresses so as to avoid delay in sending out the other volumes. Non-members of the Congress may obtain the Transactions by sending in a subscription of ten florins, Austrian money, together with two florins for postage; the amount to be sent in to the Director of the St. Rochus Hospital at Budapest. All other communications should be addressed to the editor as given below.

I am, Sirs, yours obediently,

SIGISMUND DE GERLOIRY, M.D.,
Editor of the Transactions of the Congress.

St. Rochus Hospital, Budapest, September, 1895.

"GUARDIANS AND MEDICAL OFFICERS."

To the Editors of THE LANCET.

SIRS,—As medical officer to, I believe, the largest and most populous district in the metropolis—the number of patients in my register reaching to about 2200 annually and having the attention of three relieving officers—I can speak with some experience regarding these officers and their ways. In the first place I must traverse your dictum that a relieving officer has *no absolute* discretion in dealing with an urgent case; probably he has no *practical* discretion in the actual working of the Act, as, according to the Consolidated Local Government Board Act, a medical officer might recommend this, that, or the other, but the relieving officer has absolute discretion to do just as he pleases. Of course, he takes all responsibility, should he refuse to accede to the recommendation of a medical officer and death resulted. I consider this a great flaw in the Act, conferring great power and discretion on the relieving officer, who is least able to bear it. Our board sent out instructions some two years since that a medical officer in recommending relief should state not only what food was necessary, but the actual quantity of each foodstuff. This was found to be a complete dead letter. I found that the relieving officer gave out just what he had in stock, and, as regards quantity, he had to supply not only the patient, but the wants of the family, so that my quantities were of no avail. As regards stimulants, our board are very particular, and I can say, having been in office now about nine years, that no stimulant has ever been given as out-relief.

I am, Sirs, yours truly,

September 28th, 1895. DISTRICT MEDICAL OFFICER.

"THE PHYSIOLOGY OF DEATH BY ELECTRIC SHOCK."

To the Editors of THE LANCET.

SIRS,—I am unable to see what advantage or profit can be gained from the letters of Dr. Shettle under the above heading. Vague speculations as to the influence of the earth's magnetism upon the phenomena of life are unnecessary and tedious. If Dr. Shettle has performed any experiments or collected any new facts respecting the physiology of death from electric shock, by all means let us have them, and let them be as briefly stated as possible. For my part I am entirely sceptical as to the production of electrical currents in the body by the flow of blood across the magnetic lines of force which traverse the body, and it does not even seem to me to be worth while discussing in detail many points raised by Dr. Shettle, where, in my opinion, either his premisses or his reasoning are unsound.

I am, Sirs, yours obediently,

Sept. 29th, 1895. A PRACTICAL MAN.

ERRATUM.—In Dr. Alexander Morison's letter on non-stenotic mitral bruit in THE LANCET of Sept. 28th "valvular contraction" is printed instead of *ventricular* contraction.

THE BATTLE OF THE CLUBS.

(FROM OUR SPECIAL COMMISSIONER.)

(Continued from p. 815.)

MEDICAL AID COMPANIES AT EASTBOURNE.

THE situation at Eastbourne differs fundamentally from what I have seen and described at Portsmouth. In the latter town a union of medical men has been formed to resist the encroachments of the friendly societies who seek to form lodges of children and females. At Eastbourne the question of the friendly societies has not yet been taken in hand, and for the moment the struggle is directed against the National Medical Aid Company, Limited. The method of action at Eastbourne is also totally different. For many years two assurance companies which deal mainly with the poor have done an extensive business in this town. The one is the Liverpool Victoria Legal Friendly Society and the other the Prudential Assurance Company. To secure life assurances the former of these companies became intimately associated with the National Medical Aid Company, Limited. It employs a considerable number of canvassers, and it would seem that these men find it easier to persuade people to insure against sickness than to insure their lives. The canvassers, therefore, very often open the negotiations by pointing out the advantage of paying 1*d.* per week to the National Medical Aid Company so as to secure the services of the medical men employed by that company. Then when this point has met with approval the canvasser explains that such medical insurance cannot be obtained unless the person in question also insures his life and that the life insurance is granted by the Liverpool Victoria Legal Friendly Society. This method of canvassing for life insurances proved so successful that the Prudential Assurance Company was compelled to adopt similar means. Thus the two great assurance companies which do the most business with the poorer classes of Eastbourne became, practically speaking, medical aid societies. This gave rise to serious grievances and abuses.

Early this year a private meeting was held. Some of the younger members of the profession, who suffered considerably from this state of affairs, approached the Eastbourne Medical Society. This is a purely scientific body constituted for social purposes, and not especially with a view to defending the material interests of the profession. Nevertheless, Dr. Muir Smith was allowed to read, last April, a paper to this medical society setting forth the abuses that had arisen. A resolution was carried to the effect that the medical profession should themselves organise a medical aid society, which would do the work that had previously been done in a manner contrary to the ethics of the profession and for the sole purpose of promoting the interests of commercial assurance companies. For this purpose the resolution carried at the meeting of the Eastbourne Medical Society urged that a charitable institution, an endowed provident dispensary which exists at Eastbourne, should be asked to take the matter in hand. The Provident Dispensary was requested to coöperate and reorganise on the lines approved by the general body of the profession at Eastbourne. These negotiations were not, however, successful. It was stated that the fact that the dispensary in question had endowments made it difficult to alter its rules and methods of working. One of the great objects held in view was that

Digitized by Google

the number of medical men giving medical aid should not be limited. The National Medical Aid Company at Eastbourne employed three medical officers and was willing to guarantee a minimum income. This is undoubtedly a great temptation for the young practitioner who has no opening and no private means to live upon while he creates a practice. Now, however, it can no longer be said that these assurance and medical aid companies are the only road to a poor practice. The association which the medical men themselves have formed opens its arms to all new-comers if they are fully qualified. This association was organised when the negotiations with the existing dispensary fell through. It is called "The Eastbourne Provident Medical Association" and was finally constituted in August. It began work at the commencement of September this year. The object of the association, as officially stated in its rules, is to establish a self-supporting society to enable such persons within the borough of Eastbourne as cannot pay for medical attendance at the usual rates to secure for themselves and their families the advantages of medical attendance, advice, and medicine during illness. Thus, it will be seen, the object is the same as that professed by the medical aid companies, but the management is entirely in the hands of the medical profession, and there can be no further question of utilising medical aid as a means of inducing people to insure their lives for the benefit of some financial speculation.

The Eastbourne Provident Medical Association is managed by a general committee consisting of all the acting medical staff and of a consulting medical staff of two representatives deputed by the Eastbourne Medical Society who are not on the medical staff of the association. This latter clause was inserted so that there should be some outside control, but of a purely professional kind and appointed by members of the profession not financially interested. The honorary secretary and the honorary treasurer are also medical men, but are not members of the staff. The association was fortunate in securing Mr. J. H. Ewart, the present President of the Eastbourne Medical Society, as its chairman of committee and treasurer. The post of honorary secretary is held by Dr. A. Harper. Both these gentlemen have the right to speak and vote at the meetings of the managing committee. Seven members, including the officials, form a quorum. For ordinary routine work there is a subcommittee consisting of the secretary, the treasurer, and three committeemen, three in this case forming a quorum. The first thing to be done was to appoint one or more collectors at a weekly salary and a commission. These collectors have to go round to all the members, collecting the weekly or monthly subscriptions paid to obtain medical aid, keep account of the same, and pay the money received to the treasurer once a week. The treasurer has to check the collectors' books; and every quarter, after deducting what is required to pay the working expenses, he divides the rest among the acting medical staff proportionately to the number of members on their respective lists. Thus each medical officer is paid exactly in proportion to the number of persons under his care, and he receives all the subscriptions these persons have paid except what is deducted to cover the working expenses. This completely puts an end to the exploiting and sweating of medical men. The pay may not be high; but, such as it is, no one makes any profit out of it save the medical man himself. Also the public—that is, the subscribing members—will not be urged by canvassers or collectors to seek the services of one medical man instead of another. One of the rules stipulates that "no orders or communications shall be given to the collectors except through the honorary secretary." Then, while no particular men are to be especially recommended by the collectors, the association, as already mentioned, is open to all comers. This is the rule, and, as important principles are involved, it is worth quoting the text of the rule word for word:—"Any duly qualified and registered practitioner resident in Eastbourne (not practising as a homœopath) may become a member of the staff, subject only to his appointment being approved by the committee. All members of the staff must also sign an undertaking (*a*) not to conduct clubs of their own at all (other than friendly societies registered under the Act), unless it be at rates *higher* than those of the Eastbourne Provident Medical Association; (*b*) to have no professional intercourse whatsoever with any medical man who associates himself with any of the companies known as medical aid societies or with similar institutions so long as the methods adopted by these societies include (1) canvassing for members in the interest of individual practitioners; (2) the virtual sweating of their medical officers by the inadequate remuneration offered for the work done."

The latter part of the above rule has also formed the text of a general declaration which has been presented to all the practitioners at Eastbourne. Thirty-eight medical men have signed this pledge. Only one has failed to do so, and he is not hostile to the object held in view, but objects to anything that may be considered like a trades-union. The medical profession at Eastbourne, it must be acknowledged, have acted with great public spirit, and the feeling of professional solidarity has been strong among them. At the same time it would be a mistake to imagine that a similar high and honourable spirit prevails among the medical men of every town in England. It would not be so easy to secure everywhere the same unity of action. There is at Eastbourne an exceptionally large proportion of active medical men who possess private means, and who can therefore afford to enter upon a struggle with the medical aid companies. Then there are various local social reasons which tend to give a high tone to the members of the profession who practise at Eastbourne. Thus, the above pledge was not only readily signed, but has been honourably observed.

The primary object in this movement has not been to improve the financial situation of the medical men, but to combat that system of canvassing which built up a private practice in a manner opposed to all professional rules. The canvasser, to secure his commission and to promote the interests of the assurance company he represented, would try to persuade persons to leave their medical man and to accept instead the services of the practitioner who was the servant of the association or company for which he worked. In thus touting it was not to the canvassers a matter of professional etiquette—it was merely a matter of business; their only object was to obtain customers and to gain commissions. They used the medical man as an article of trade, as a sort of decoy duck so as to obtain subscribers to their assurance companies. The methods, the arguments, and the language employed by these canvassers was altogether derogatory to the dignity of the profession. It was intolerable that medical men should be thus utilised as a bait for the running of commercial companies. The question of inadequate remuneration was altogether a secondary consideration. The National Medical Aid Company, Limited, used to collect a penny per week from adults and a halfpenny per week from juveniles; but on a joint protest being made by its medical officers in 1893 the subscription was raised to a penny for juveniles. From this sum 15 per cent. was deducted for working expenses and the rest given to the medical officers. But the company also charged and kept for itself 4*d*. for entrance fee, 2*d*. for first card, and 1*d*. for other cards. It further enforced the renewal of cards when they were soiled. Still, the general impression is that it is not from these small sums or from the 15 per cent. deducted from the subscriptions that the main profits are made. The chief object is to induce people to insure their lives or join a burial fund; and the fact that so many persons thus insured ultimately let their policies lapse adds immensely to the profits of the undertaking.

It must also be noted that to the canvasser for a company the question of wage limit is of no importance whatsoever; on the contrary, far from desiring that only poor people should subscribe for medical benefits, the canvasser prefers those who are comfortably situated, for they are more likely to pay large premiums for life insurance. Thus, the material interests as well as the dignity of the medical profession were compromised. Such are some of the principal reasons which have led to the formation of the Eastbourne Provident Medical Association. Having decided upon this course of action, the three medical officers in the service of the National Medical Aid Company, Limited, gave a three months' notice of their intention to quit. They employed the interval in explaining to their patients the motive of their resignation and that they would secure the same advantages by joining the new association which the profession had themselves formed. There seems to be but little doubt that the great majority of the members will follow their medical men and join the new association the latter have organised. Then all those practitioners who had private, medical, or slate clubs of their own have brought over all their members to the new association. This was the more easy to do as in most instances it did not involve more than a change of name. The members

Digitized by Google

pay about the same subscription and are attended by the same medical man. There are already nine practitioners on the medical staff of the Eastbourne Provident Medical Association, and this is a great practical advantage. No benefit club, no medical aid company, could possibly offer its members so large a choice of medical men in so small a town as Eastbourne. As a rule, members joining such organisations have no choice at all, but must accept the services of the medical officer of their society who resides in their district. For these and other reasons the propaganda in favour of the new association was so successful that the three medical officers in the service of the National Medical Aid Company were not required to serve the full three months of their notice. They were set free at the end of the second month, for fear, perhaps, that they would persuade all the members subscribing to the company to subscribe in future to the association founded and managed by the medical men themselves. The National Medical Aid Company, driven into a corner by the resignation of its fully qualified medical officers, has had to import medical assistance. No sooner had the gentleman selected arrived at Eastbourne than a courteous appeal was addressed to him not to place himself in opposition to the interests and the unanimous opinion of the medical profession at Eastbourne. He, however, replied that it was for him a question of £ *s.* *d.*, and that if he refused the post there were many others quite willing to take it. He is alone to do the work of the three medical officers who resigned, but there is not so much to do, for so many of the members of the National Medical Aid Company have now left that organisation to join the Eastbourne Provident Medical Association. Consequently the presence of this gentleman at Eastbourne does not cause much apprehension. Still, the question remains as to what is to be done with the practitioners who in such struggles serve medical aid companies, who take sides against the interests of, and help to thwart the efforts made to maintain the dignity of, the profession

With regard to the Prudential Assurance Company there have been no difficulties at Eastbourne. This company does a very large insurance business with the poorer sections of the Eastbourne population and never desired to complicate this business with the giving of medical aid. The competition, however, of the Liverpool Victoria Legal Friendly Society compelled it to add medical aid to the ordinary inducements offered to its customers. For this purpose the Prudential Assurance Company asked two or three medical men to allow it to use their names. The agents of the Prudential Company were, nevertheless, strictly enjoined not to canvass for medical men and were given no incentive to do so. If a person who was urged to insure his life, on his own accord asked to be also insured against sickness, the agent mentioned the names of the medical men, but not otherwise. The agent received no commission if the medical insurance was effected; it only enabled him to offer the same advantages as the rival life insurance company. The arrangement, also, is a purely local affair and not a general custom with the Prudential Assurance Company. If, though not in any way urged to do so, the subscriber to a life insurance also desired medical aid he had to present himself to one of the medical men suggested by the agent, who examined the person and imposed his own wage limit. The medical man then sent his own collector for the weekly or monthly payments, paid his own expenses of collecting, and kept all that remained for himself. Under these circumstances the Prudential Assurance Company has no objection to the formation of the Eastbourne Provident Medical Association; on the contrary, all its members that desire medical aid have been transferred to this association. The Prudential Assurance Company is working in harmony with the medical profession and advises all its customers to join the organisation formed by them. Though this is of no direct financial advantage to the Prudential Assurance Company it enables the company to attend strictly to its own business instead of dabbling with medical aid; and to those of its customers who want medical aid the company can offer a choice of nine medical men of good reputation, while its rivals can now only command the services of one single practitioner.

The Eastbourne Provident Medical Association has boldly grappled with the vexed question of the wage limit. First, it stipulates in its rules that no person can become a member who is in receipt of parochial relief. All applicants must be examined and declared to be in good health by one of the medical officers, and persons of indifferent health can only be admitted at special rates to be determined by the committee. Then the rules explain that, "although a most desirable matter, it is very difficult in practice to adopt a hard-and-fast wage limit, and therefore it would appear that the best way of preventing abuse of the association by persons who are too comfortably off will be by leaving absolute discretion in the hands of the committee to consider the case of every applicant on its own merits."

The fact is that at Eastbourne, more especially, a hard-and-fast rule would not be fair. Living is very dear at Eastbourne, and rents are particularly high. The average rent of a workman's cottage is 8*s.* a week; no cottage can be found under 6*s.*, and many working men have to pay more than 10*s.* a week for rent. Provisions generally are dearer than in large manufacturing towns, and great distress prevails in the winter, for most of the artisans at Eastbourne depend on the building trades. Even the lodging-house keepers are often in sore difficulties, for they have enormous expenses, and they are not always certain of letting their apartments. Thus, there are several good reasons for admitting a high wage limit, and the matter is left in a measure to the discretion of the committee. Nevertheless, there must be a general rule, and the Eastbourne Provident Medical Association has not hesitated, in spite of the above difficulties, to establish such a rule. It is, therefore, stipulated as a general principle that for families, if the combined incomes of the parents do not exceed 35*s.* a week, the payment shall be 2*d.* per week for each person above fourteen years of age, and 1*d.* a week for each child under that age. If the combined incomes do not exceed 25*s.* the charge shall be 1*d.* a week for parents and children alike. It is expected that the whole of the family will be entered on the lists, exception being made, however, in the case of any members who may already be members of a registered friendly society. In large families not more than six children will be charged for. When children reach their fifteenth year they can continue their membership by paying the subscription charged for adults. Domestic servants are not admitted as members, but a member who subsequently becomes a domestic servant does not forfeit the privileges of membership. For single persons the wage limit is fixed at 20*s.* per week. The committee reserve the power of giving a quarter's notice and then removing from the books the name of any person who is ascertained to be in receipt of such an income as to render him or her unsuitable for membership. Such persons may, however, give explanations to the committee in self-defence. A charge of 2*d.* is made for cards of membership, the payments must be made in advance, a member more than a month in arrears loses his rights, and his name is effaced from the books if two months in arrears. Those who desire readmission must pay all the arrears due or such part as the committee may require. With regard to confinements, the rule is that the member shall employ the medical man on whose list she is inscribed, but if she prefers to employ some other medical man she must forfeit her right to the former's professional services for a period of six weeks. The fee for confinement is fixed at 15*s.*, payable at any date previously to the confinement. The same charge is made for premature confinements. For vaccinations only calf lymph is employed, and this at the bare cost of the lymph. Special rates, which have not yet been fixed, will be charged for fractures, dislocations, and major surgical operations. Members on joining select the medical man they prefer, but they must give a quarter's notice if they wish to change. Finally, it is stipulated that an annual meeting of all the local members of the profession shall be held to hear the report of the Eastbourne Provident Medical Association. The committee may by a two-thirds majority alter the rules if all the members have a clear twenty-eight days' notice of such proposed alteration.

Such, then, are the rules of this benefit society which the medical men have themselves organised. They have sought to solve the problem by taking the whole matter into their own hands, and the experiment will certainly be watched with keen interest by the whole medical profession.

Eastbourne, September.

SKETCHES FROM RHENISH WATERING-PLACES.

(BY OUR BERLIN CORRESPONDENT.)

THE number of watering-places and health resorts on the Rhine and in its vicinity is so great that a medical man who can spare but little time for the purpose will find it nearly

Digitized by Google

impossible to visit them all. Some selection being therefore essential, I first directed my steps to Homburg. It is hardly necessary to describe this place to English readers, as perhaps no other foreign watering-place is so well-known in England, neither has any other acquired such a specially English character as Homburg. On arriving at the station after half an hour's journey from Frankfort the English visitor is surprised to hear the drivers of the public vehicles receive strangers whom they suppose to be of British origin with the words, "Carriage, Sir," or something equivalent which they might have learned from the cabmen at Charing-cross or Victoria Stations. On passing through the town one might almost think that English is the vernacular, such advertisements as "Furnished rooms to let," "German rusks," "English perfumery store," &c., being everywhere visible. The people thronging the streets are like those to be seen in a fashionable English resort patronised by seekers after health or amusement, so much so that were it not for the soldiers of the garrison and some other types who prove that one is in Germany, one would seem to be in Bath or Bournemouth. I, indeed, often expected to meet at the next corner either a party of the Salvation Army, or minstrels with blackened faces, or some other of the street scenes peculiar to English towns. Homburg owes its popularity in England to two causes: the first is that the frequent and prolonged visits of the Prince of Wales have made it fashionable for the higher classes and their imitators to go there. With real pride the head waiter on the Kursaal terrace told us that he was expecting to have His Royal Highness and seven English dukes at dinner that evening, of course not mentioning the crowd of earls, viscounts, and other aristocrats of less degree. It is really a very pleasant spectacle to see the Kursaal terrace on a lovely summer evening, crowded with distinguished-looking people, all in evening dress, taking a short after-dinner walk or listening to the musical performance of the admirable Kursaal band. The other cause of Homburg's celebrity—a more valid one and of more medical interest—is its fresh and bracing air, which attracts people in search of a comfortable and charming summer resort, and the multiplicity of its springs and other therapeutical arrangements which appeal to patients suffering from chronic catarrh of the stomach, bowels, or biliary organs, as well as to the gouty and the anæmic. In addition to the natural saline and ferruginous waters, all kinds of artificial baths are supplied in a new establishment built close to the springs. The baths are heated by pipes placed underneath in order to avoid undue loss of carbonic acid. An inhalation-room is connected with the bathing establishment, whilst hydropathic and electrical treatment and massage are performed in special departments. No medical man visiting Homburg should omit a trip to the Falkenstein Institute for Phthisical Patients. This hospital is situated near Cronberg, the residence of the Empress Frederick, about five miles from Homburg, and was one of the first where the open-air treatment of the phthisical was used. It is built on the southern side of the Taunus mountains and is protected from the cold northern winds by these mountains, which ascend gently from the valley of the river Main and form a vast amphitheatre around Falkenstein, Cronberg, and the adjacent places. This sheltered situation makes Falkenstein comparatively warm in winter, and the patients can leave their rooms nearly all the year round. As Falkenstein is about 400 metres (1300 feet) above the level of the sea the air is not so relaxing as might have been supposed from the nearly total absence of atmospheric currents. The patients live partly in a kind of central building, which also contains the dining-hall, reading-room, billiard-room, &c.; all well ventilated and heated by hot water, and partly in cottages built in the large park belonging to the establishment. The advanced cases rest nearly all day on couches in the park, whilst the more vigorous are allowed to walk in the surrounding forests. There are three resident physicians in the hospital, and consultants from Frankfort attend the patients when required. The physicians of the hospital principally insist upon a liberal diet, with plenty of milk, whilst medicine is hardly ever prescribed. The institution is patronised by many Germans and foreigners, but the medical men told me that English visitors are very rare, and they would be glad if the profession in England would devote some attention to this establishment. Prominent among its advantages is the circumstance that patients there are under constant medical supervision, and therefore cannot behave in the inconsiderate fashion not unknown in Davos and other places where hotel life is the recognised system. The Falkenstein institution was founded by a citizen of Frankfort, and its regulations were based upon the principles laid down by the late Dr. Brehmer of Görbersdorf. The charges for board and residence, although moderate, are much too high for the poorer classes; but the proprietors do not intend to make money by their enterprise, and, according to the rules of the company the profits, when they have reached a certain amount, are to be employed in the construction of a free hospital for indigent patients.

Travellers from Homburg to Wiesbaden must proceed to Frankfort and start from its central station, one of the largest and certainly, from an architectural point of view, the finest in existence. Only a short journey has to be made, passing through Höchst, the seat of the great "Farbwerke," a very extensive manufactory of chemical products, which supplies nearly the whole world with drugs and chemicals such as antipyrin, phenacetin, carbolic acid, aniline colours, &c., including Professor Behring's antitoxin for diphtheria; the forest of high chimneys belonging to this vast establishment is visible from the railway. We then pass through Castel, opposite to the town of Mayence with its hundred towers on the other side of the Rhine, and in forty minutes from Frankfort come to Wiesbaden. On first arriving there the traveller can scarcely believe himself to be in a health resort, all the appearances being those of a considerable town with long and busy streets and a puffing steam-tram. But on coming nearer to the visitors' quarter, with its beautiful and well-shaded park, its fine kurhaus, and the Kochbrunnen, where crowds of patients are assembled to take the waters, the scene is totally changed. Wiesbaden, indeed, unites the advantages of a thriving town of about 80,000 inhabitants with the requirements of a highly fashionable health resort. It is, therefore, not only a place where people go for the benefit of their health, but has also for a long time been a favourite residential locality for retired military officers, civilian officials, and business men, who appreciate its genial climate with its additional attractions of theatres, concerts, and other amusements; while they can live there as comfortably as in Berlin or Frankfort and at much less expense than in those towns. In summer the temperature is rather high, but, nevertheless, we saw a number of patients; the principal seasons are, of course, the spring and autumn, when all the hotels and boarding-houses are overcrowded; but even during winter there are many patients, as the climate permits them to enjoy the fresh air during a great part of the day. Wiesbaden is the paradise of the rheumatic. They can take hot alkaline baths without going out of doors, as nearly all the hotels are connected with bathing establishments; there are also excellent arrangements for massage, hydropathic treatment, and other therapeutic expedients necessary for this class of sufferers.

A short distance from Wiesbaden is Rüdesheim, celebrated not only for its wine, one of the best produced in this fertile country, but also for the national monument, a gigantic statue of Germania, erected on the top of the Niederwald mountain as a memorial of the revival of the German Empire, and visible from the train as it crosses the Rhine for Bingerbrück. From this station Kreuznach is reached by rail in a very short time. Kreuznach is widely known on account of its saline springs containing iodine and bromine, and also on account of its mother liquor, which is obtained by partial evaporation of the water and is exported to every part of the world. The brine works are situated about twenty minutes from the town, and many children, especially such as are tuberculous, may be seen sitting or playing in the large open halls of the brine works where they are sent to get the benefit of the salt-laden air. As in Wiesbaden, the hotels here have their own bathing arrangements. Kreuznach, too, like every watering-place of the better class in Germany, has its Kurhaus; the population is almost cosmopolitan and the whole place has a fashionable aspect. Those who wish to use the same springs as at Kreuznach, but desire a quieter locality may stay at Münster-am-Stein, a little place about half an hour's drive from Kreuznach, where there are very large brine works and wells of an identical kind. The efficacy of the water is, of course, the same, whilst everything is more simple and less expensive than in Kreuznach. But what makes Münster preferable is the circumstance that not only are the environs much more attractive, but the brine works are in the town and not outside it as at Kreuznach. These two sister towns are very

Digitized by Google

hostile to each other, and it is really comical to see Kreuznach insinuating that Münster has falsified the analysis of its spring, and Münster asserting that the so-called Kreuznach mother-liquor comes mostly from its own brine works. These local quarrels often find expression in the advertisement columns of the German medical and lay press, to the great amusement of their readers. The Rhine steamer brings us from Bingerbrück, on the most beautiful part of the Rhine, to Niederlahnstein, where we again take the railway for Ems. Considerations of space compel me to abstain from a more detailed description of this watering-place, with its alkaline saline springs, used from remote antiquity for catarrhal affections of the air passages, the respiratory and digestive organs. I must confine myself to the statement that in respect of hygienic and therapeutic arrangements Ems is one of the best appointed places, that the inhalation-rooms which are of so great importance in laryngeal cases are first rate, and that the town itself, nicely situated on both sides of the river Lahn, is very attractive and clean looking. Ems, indeed, needs not to be recommended to the profession, as patients from nearly every part of Europe are sent there by their medical advisers. Here we terminated our inspection of the health resorts, and in the character of ordinary tourists went on over Coblenz and the Moselle valley to ancient Trier, once a residence of Roman emperors.

THE FIFTH INTERNATIONAL CONGRESS OF OTOLOGY.

(FROM A SPECIAL CORRESPONDENT.)

(Continued from p. 814.)

TUESDAY, Sept. 24th, at 9 A.M., found the Congress steadily at work, overtaking in the order officially settled for each sitting the several communications and memoirs on the agenda paper. The attendance was good, and Professor Politzer, as president for the forenoon, maintained the business at a high level of efficiency and dispatch.

Anything like a detailed account of each paper as it was read and discussed would be impossible within the limits of a letter. To say nothing of the fact that the successive "conferenzieri," as Italians style the authors of such communications, got through their matter with a rapid elocution not always easy to follow, the few remarks interjected at the close by a specially interested auditor did not always reach the point of serious criticism, such as could give rise to really fruitful discussion. Indeed, the majority of the "Congressisti" seemed to content themselves with "general impressions," awaiting the opportunity of mastering the views and counter-views advanced when the officially edited "Atti" would be in their hands. In these circumstances all that even the "special correspondent" can do is to report the proceedings in swallow fashion—"skimming and dipping."

An exceptionally interesting and instructive thesis was that of Professor Gradenigo of Turin on the General Treatment of Internal Otitis, which formed, indeed, the main feature of the forenoon sitting. In the afternoon Dr. Gellé presided, when Dr. Corradi of Verona read his communication on Traumatic Perforation of the Tympanum, on which, again, an interesting discussion arose, the chief interlocutors being Professor Politzer and Dr. Gellé. He was followed by Dr. Ferreri of Rome, whose carefully elaborated exposition of Senile Alterations in the Middle Ear was listened to with marked attention and criticised by Professors Politzer and Gradenigo and by Dr. Gellé. Matter of somewhat inferior interest ensued until Dr. Delstanche of Brussels brought back the attention of the audience to a high pitch by his eminently lucid and practical paper on the Employment of Liquid Vaseline in the Treatment of Affections of the Middle Ear. The author's great experience and successful practice lent particular weight to his views, which were confirmed by some of his critics, while others asked for further information as to the mode of injecting the vaseline, as to the quality of the liquid (whether sterilised or not), the necessity or otherwise of adding iodoform, and a number of similar points. The sitting lost none of its animation when the next memoir—the concluding one for the day—was introduced by Dr. Macnaughton Jones. His subject was "Turbinal Hypertrophy," or, to give it the full title it bore in French, "Hypertrophie Turbinale et ses Relations à la Surdité, spécialement à l'égard de l'Opération de la Turbinotomie." Dr. Macnaughton Jones gave a masterly review of the subject as dealt with by previous otologists, and summed up his own conclusions as follows: 1. Turbinal hypertrophy must be regarded as a serious complication of deafness and the cognate aural affections; in those cases in which it precedes the aural symptoms we may justly regard it as being their principal cause. 2. In all cases in which this hypertrophic change is discovered active therapeutic measures, of which galvano-cauterisation is the chief, ought to be put in practice to reduce it. 3. Deviation, or distortion, or morbid growth of the septum is rarely, perhaps never, the cause of deafness, and they become so only in cases in which they complicate the turbinal hypertrophy. 4. In all cases in which we find that the occlusion of a nostril is in part due to the deviation of the septum or to a growth that deviation must be rectified. 5. Turbinotomy is indicated and ought to be reserved for those cases in which, whether in consequence of the bulk or of the nature of the growth, it is vain to expect improvement from any other treatment. This may present itself in a comparatively very small proportion of aural cases. Dr. Macnaughton Jones was so thoroughly master of his ground, shown in his preliminary digest of received, and especially of contemporary, opinion that his highly appreciated paper was exempt from criticism, leaving him nothing to acknowledge but the applause of the sitting, which thereafter rose for the day.

As on the 23rd, so also to-day (Tuesday), the evening closed with an entertainment, which in the latter case took the form of a brilliant banquet given by the President and Madame Grazzi to the Congressisti and their ladies. The guests numbered more than eighty, and enjoyed the evening as thoroughly as excellent *cuisine*, exhilarating music, and an all-embracing geniality entitled them to do. The after-dinner oratory was of a highly successful order, begun by Dr. Grazzi in French, and continued in the same language by Dr. Delstanche, till Professor Politzer set a laudable example by addressing the company in Tuscan of the purest quality. Others emulated the Austrian consultant, but the majority of the after-speakers relapsed into their native tongues, of which we had nearly every specimen, from the English of London, Edinburgh, and Pittsburg to the German of Breslau and the Spanish of Madrid. The speakers vied with each other in their acknowledgments of the hospitality of their reception in the Tuscan capital, and particularly of the grace and tact with which Madame Grazzi did the honours of the Palazzo Peruzzi. After dinner the evening closed agreeably in patrolling the magnificent suite of rooms in that historic palace, admiring the frescoes of the artist whose name it bears, and joining in pleasant comparisons of the impressions already formed of the "City of Flowers."

The sittings of Wednesday, Sept. 25th, were chiefly noteworthy for Dr. T. Barr's paper on the Treatment of Intracranial Abscess consequent on Maladies of the Ear; Professor Gradenigo's contribution to the Endo-cranial Surgery of Otitic Complications; Dr. St. Clair Thomson's observations no Antisepsis and Intra-nasal Medication; and, above all, for Professor Politzer's original and epoch-making memoir on the Present State of the Pathological Anatomy of the Labyrinth. Of Dr. Barr's paper I will only say that owing to his regretted absence through illness it was entrusted to the competent charge of Dr. Urban Pritchard, and that it aroused and maintained the interest of a crowded sitting to the close. Professor Politzer's memoir I need not attempt even to summarise, as its publication, with the cordial consent of the author, has been reserved for THE LANCET. Suffice it to say that as its appearance on the agenda paper proved the chief attraction of the Congress—many otologists having come from a great distance on purpose to hear it—so it amply rewarded the close attention it commanded from the audience, whom it kept in keenest interest until its author, amid successive rounds of applause, resumed his seat. From labour to refreshment marked the next stage of the Congress, which was entertained by the Commune at afternoon tea in the magnificent *salons* of the Palazzo Vecchio, where the ever courteous and kindly President, Dr. Grazzi, presented the Congressisti and their

Digitized by Google

ladies to the Cavaliere Artimini, who, in the absence of the Syndic, "did the honours."

Next day (Sept. 26th) brought the business of the Congress to a close, the feature of the forenoon sitting being Professor Politzer's demonstration of the Anatomy of the Ear, illustrated by beautiful preparations, osteological and other, which, as they passed from hand to hand, evoked audible murmurs of admiration. The papers read maintained the high standard, scientific and clinical, of the majority of those sent in, among them being that of the President, Dr. Grazzi, on a Case of Complete Deafness consequent on an Acute Meningitis "par Diplococcus de Fränkel," in illustration of which the patient (a female child) was exhibited to the audience; that of Dr. D'Aquanno (Palermo) "Sur la Paracusie de Willis"; and that of Dr. Secchi (Bologna) on the Physiology of the Middle Ear. Another feature of this sitting, as of previous ones, was the exhibition of otological instruments and appliances. Dr. Macnaughton Jones had interested the Congress by his auto-insufflating aural bag for respired air and vapours, his magnifying aural speculum, pliable nasal bougies and dilators, his turbinotome and scale with rule for operation on the mastoid, antrum, tempero-sphenoidal lobe, and cerebellum; and on Thursday morning Professor Gradenigo exhibited an original and ingenious "diapason," ably criticised by Dr. Dundas Grant. Mr. Cresswell Baber followed with a demonstration of new additions to the "armamentarium otologicum," which was generally admired. Detailed notice of these I need not attempt, any more than even an enumeration of the concluding papers, interesting though some of them were. In the afternoon the Congress adjourned to the *aula magna*, where President Grazzi formally closed its labours with cordial congratulations to its members and office-bearers on the results. Other speakers followed, among them Professor Politzer, who eloquently thanked the secretaries for their assistance, and with a parting word from the Cavaliere Artimini, representing the Syndic, the fifth International Congress of Otology was an event of the past.

In the afternoon a trip to Fiesole was greatly enjoyed by the "emancipated" Congressisti and their ladies, who found much to admire in the Cathedral, the Etruscan Museum, the finely preserved ancient theatre, the baths and Cyclopean walls still in process of excavation, and, above, all in the magnificent panorama of the Apennines. The noble hexameters of Gray,

"O Fæsulæ, amœna
Frigoribus juga," &c.,

recurred to more than one enraptured Congressista, and may be thus rendered:

"Oh hills of summer coolness, Fæsulæ,
The zephyr's haunt! By Pallas' boon you shine,
Ensilvered with her own gray-glistening tree,
The jewel of Etruscan Apennine!
No more from Arno shall the joy be mine
Your villas and verandahs to admire
Around your forehead circling, line on line,
To see your dome outsoar the cypress-spire,
And roof o'er rustic roof hang higher still and higher."

At 8 P.M. the Congressisti and their ladies, with other guests, to the number of 150, sat down in the Politeama to a sumptuous banquet, at which Dr. Grazzi presided. The evening was a highly agreeable one, the speech of the occasion among many effective ones being Professor Politzer's who interwove with it a eulogy of Florence, in which he revealed a wonderful knowledge and appreciation of the past glories and present attractions of "Our Lady of Flowers." By 10.30 P.M. the company separated with cordial anticipations of such another successful reunion in London, the next seat of the Congress in 1899.

Florence, Sept. 27th.

THE MEETING OF THE ASSOCIATION OF GERMAN NATURALISTS AND MEDICAL MEN.

HELD IN LÜBECK FROM SEPT. 16TH TO 21ST.

(FROM OUR BERLIN CORRESPONDENT.)

THIS purely scientific association is one of the oldest in Germany, and it now assembles for the sixty-seventh time. Till 1888 it was not an association properly so called; medical men and naturalists met every year at some town which had been selected at the previous meeting. There was no permanent committee, but a president, secretaries, treasurer, &c. were elected for each session, and their office only lasted till its close, the preparatory business being done by medical men and naturalists of the locality selected. Every member of the medical profession or recognised naturalist could become a member, the membership of course holding good during the respective session only. This was the state of matters till 1888, when a change became necessary because the association, having by that time funds in hand and a library supplied by donations, required a more permanent administration. At the Cologne meeting of 1888, therefore, by-laws and rules were passed by which the formerly free association was changed into a regular society. A permanent committee was elected and the condition of membership modified. A medical man or naturalist desiring to become a member was to be elected by the committee, and his membership then was a perpetual one. Besides the ordinary members, other medical men and naturalists were admitted to the meetings as participating members, "Theilnehmer," but they had no right to read papers or to take part in the debates, and their membership terminated at the end of the congressional sessions. The scientific business of the society is carried on partly in three general sittings, when papers of a more general interest are read by leading men, and partly in the special sections, the number of which this year was no less than thirty three.

The First General Meeting, on Sept. 16th.

The Mayor, in the name of the senate and the presidents of the medical and of the naturalists' societies of Lübeck, welcomed the association. The President, Professor Wislicenus (Leipzig), expressed thanks for the hearty reception and then gave an account of the society's affairs.

Professor Klebs read a paper on Some Problems concerning the Physiology of Generation. He said that whilst the structure even of the most complicated organs is completely investigated the function of many of them is still little known. The problem of generation, for instance, is still unsolved. It is very important to know if generation can be influenced by external conditions. The general opinion is that the generative power is essential to the nature of the beings and therefore withdrawn from our researches; this opinion is totally wrong. There are two modes of generation in plants and animals—the sexual and the asexual. The experiments of Professor Klebs prove that asexual generation, which exists in the algæ, the ferns, the fungi, and in the lower plants, is strictly dependent upon external influence, upon light, temperature, organic and inorganic stuffs. The physiologist may, by his knowledge of the respective agents, compel plants or animals to generate or prevent them from generating. But also the formation of sexual organs may be accelerated or suppressed according to the will of the physiologist. All conditions which tend to suppress the growing of the lower plants accelerate their sexual generation; generation and growth are adversaries, of which one only can prevail in the organism and requires the whole power supplied by the nutrition. Full light is favourable to the formation of the sexual organs, whilst in softened light the nutritive and growing power prevails, the generative organs degenerating to sterility. In looking upon the fact that in the more highly organised animals sexual generation is exclusively present, one becomes induced to ask why this complicated mode has taken the place of the more simple and effectual asexual one. Some zoologists are of opinion that sexual generation is a primary function of the organism. They found their rather mystic opinion, among other arguments, upon the fact that infusoria generate only for a short time in an asexual way, and that they degenerate if they are not from time to time sexually impregnated. But many lower plants, when their sexual generation is artificially suppressed, may be kept fresh and continue to grow. Many other organisms, such as bacteria, fungi, &c., have exclusively asexual generation. Also the sexual generation can be suppressed by artificial agents, such as acids, and stimulated by other means. The physiologist is able to make plants and animals to a certain degree grow and generate as he likes, and no mystical power exists which may determinate these functions.

After Professor Klebs's rather theoretical paper Professor Behring rose to deliver a very practical speech on the Results and the Objects of Serotherapy. The celebrated discoverer of the diphtheria antitoxin began by pointing out the great value of statistics in determining the efficacy of a new remedy. Alluding to the antitoxin debate in the Berlin

Digitized by Google

Medical Society,[1] he remarked that the time was passed when medical men ought to use expressions like "genius epidemicus" and attribute to it the degree of mortality. He stated that vaccination had succeeded in compelling the genius to withdraw, and that the genius epidemicus of small-pox epidemicus of malaria must in a large proportion of cases leave the victim when quinine is used. To prove that antitoxin had the same effect on the diphtheria genius was the purpose of his speech. In the above-mentioned debate one of the principal arguments of Professor Behring's adversaries had been the alleged fact that, whilst formerly grave cases of diphtheria only were treated in hospitals, since the antitoxin period a greater number of mild cases were received. This argument could easily be rebutted by statistics, these showing that in 1893–94 55·9 per cent. and in 1894–95 52·9 per cent. only of all diphtheria cases were treated in hospitals. The total hospital mortality was 21·1 per cent. and that of home patients 26·8 per cent. In the four years preceding the antitoxin period there were in Berlin 15,958 cases with a mortality of 5617, or 35·2 per cent. The year 1894–95 showed a widely spread epidemic in Berlin, not less than 5578 cases having been registered by the health officer, a fact not very favourable to the statement of a mild genius epidemicus. If the mortality had been the same as in the other years 1963 patients would have died, whereas last year's mortality was only 1056 patients; in the antitoxin era, therefore, 907 lives were saved. A most striking result, too, was afforded by the comparison of two hospitals, one having used and the other having abstained from employing antitoxin. In the Charité Hospital in the first class there were 299 patients with 53 deaths, or 16·7 per cent.; in the Bethania Hospital, where antitoxin was excluded, there were 249 patients with 112 deaths, or 43 per cent. This exclusion of antitoxin Professor Behring sarcastically declared to be of great value to the statistics, but not so in the interests of the patients of the Bethania Hospital. A collective investigation of home-treated cases showed a mortality of 7 to 8 per cent. only—i.e., half the number of hospital cases. There were also numerous other interesting statistical tables reported by Professor Behring, which I must abstain from mentioning. If in the future the quantity of the remedy injected was sufficiently great, and mild and grave cases were both treated by antitoxin, the statistics surely would be still better. An early application, too, must be regarded as a matter of extreme importance, and, as it was proved by Escherich's and Bose's communications, that in that case tracheotomy might be avoided. The mortality of this terrible illness, Professor Behring was sure, could be made to fall to 5 per cent., but if only 75 per cent. of deaths were avoided 45,000 lives would be yearly saved in Germany. Even now, when the application of antitoxin is still in its infancy, the mortality had fallen to 75 per cent. of the former amount, so that 15,000 people had escaped from death. The immunising effect was not yet so obvious as the curative one, because the number of cases reported was still too small; but up to the present no case had occurred where real harm had been done by the prophylactic injection. After having shortly spoken of the anti-tetanic and the anti-choleraic serum, Professor Behring closed by saying that everything which he and others had done in this direction was based upon the immortal researches of Professor Koch.

The Second General Meeting, on Sept. 18th.

Professor Riedel (Jena) first read a paper on Surgical Operations on the Skull. As, of course, the audience was not composed of medical men only, he dealt with the subject in a somewhat popular manner; therefore, a short account will be sufficient. He mentioned that trephining was long ago performed by the Incas, the ancient inhabitants of Mexico, and also by the Romans, as the discoveries of Pompeii and Herculaneum proved. To-day we trephine for fractures, for hæmorrhage from the meningeal arteries, and for cysts, suppuration, and tumours. In the last case the principal obstacle is the difficulty of diagnosis and localisation. Of 100 tumours six only are found and operated on; in three of those death occurs from the operation, so that 3 per cent. only have a favourable issue. Another drawback is that often a great deal of the brain must be removed owing to the operation. The results of trephining for injury are better. Suppuration often arises from apparently insignificant causes, and Professor Riedel mentioned a case where a cerebral abscess followed a slight wound received in a student's duel where the necessary antiseptic precautions had been neglected.

After Professor Riedel, Professor Victor Meyer (Heidelberg) read a paper on the Problems of Atomicity.

(To be continued.)

[1] THE LANCET, Jan. 19th, 1895.

THE IRISH WORKHOUSE INFIRMARIES.

(BY OUR DUBLIN CORRESPONDENT.)

MANY allusions have been made in THE LANCET during the last four months to the unsatisfactory condition of some of the workhouse hospitals of Ireland. It will be remembered that early in June a circular was addressed by the Irish Medical Association to the medical officers of all the Poor-law infirmaries, the replies to which disclosed the absolute necessity for a widespread reform in the management and nursing arrangements of many of these institutions. On June 25th an influential deputation, organised by the Irish Medical Association, and consisting of its chairman and secretary, the President and Vice-President of the Royal Colleges of Physicians and Surgeons, the President of the Royal Academy of Medicine, &c., waited upon the Local Government Board and made some suggestions the outcome of which was a circular letter from the Board directing the attention of the Poor-law guardians to "the alleged insufficiency of the nursing and requesting that the medical officer of each workhouse might be called upon to furnish a report on this most important matter." Many irregularities and defects in the nursing and administration of the Poor-law infirmaries have since been brought to light.

The South Dublin Union Infirmary has been looked upon as a model institution, but Mr. Lenehan, one of the guardians, recently made the suggestion that trained nurses should be employed to see after the patients there. His statement, and the comments of the *Irish Figaro* on the matter, had the effect of calling forth a letter addressed to that journal by Sir Robert Sexton, the Protestant and Conservative chairman of the board of guardians, in which strong testimony was made to the improvement in moral tone, in regularity, cleanliness, &c., which had followed the introduction of the members of a community of nuns—the sisters of mercy—as nurses to the institution.

In the meantime an investigation was held at Athlone by one of the Local Government Board medical inspectors as to the condition of the union infirmary there, in reference more especially to the nursing arrangements, and a correspondence took place between the Local Government Board and the board of guardians, in which the former threatened to dismiss the board of guardians unless their requirements as to the nursing were carried out. The guardians wished to appoint as nurse in the infirmary a nun belonging to a religious community of ladies, while the Board refused to sanction the appointment on the ground that the lady was not a trained hospital nurse. The guardians then suggested that she should be duly trained in a Dublin hospital, to which the Board assented. According to the local papers the Roman Catholic Bishop of the diocese now intervened and refused to permit this arrangement, giving as a reason that it was against the rules of the religious order to which the lady belonged for her "to undergo training in the manner required." The guardians then declared that they would adhere to their appointment of the lady mentioned, notwithstanding the threat of the superior court to dissolve them. That threat has been promptly transmuted into action. The guardians have been dismissed by a sealed order, dated Sept. 21st, and two paid guardians, at an annual salary of £250 each, appointed in their place. The above is a plain statement of the condition of affairs at the Athlone Union, the situation not being caused by any difficulty from want of funds. Mr. Gerald Balfour, the Chief Secretary for Ireland, not long since stated in the House of Commons, and doubtless with perfect accuracy, that the shortcomings in some of the union workhouses in the West of Ireland were really caused by the poverty of the districts. This excuse does not apply to the board of guardians at Athlone, for it has transpired that the union there is in an excellent financial position, and, according to the statement of the

Digitized by Google

late chairman of the dissolved board, has at present a balance of over £2000 to its credit.

A leading article of a somewhat unwise and intemperate character appeared in the *Freeman's Journal* of Saturday last headed "Intolerant Bureaucrats," in which the action of the Local Government Board in this matter is attributed to religious bigotry. According to the report in that journal the Roman Catholic Bishop stated that "the nurse (who had been at the Athlone Infirmary for five years) had actually been trained for five years. They, the nurses" (he is said to have stated) "have undergone training at least as good as they could undergo in any Dublin hospital." Now it seems unnecessary to say that nurses in Dublin, as in London and elsewhere, are now obliged to undergo a course of study and training of at least two years' duration in a duly recognised clinical or teaching hospital in which classes of students of medicine are also trained or taught. The probationer nurses are taught not only the mere technique of nursing the sick, but also the principles which underlie it. They are obliged to learn the elements of anatomy, physiology, medicine, and surgery in order that they may be qualified, not alone to strictly carry out, but also to fully understand and appreciate the directions of a medical man in charge of a patient. Their experience and training in a teaching hospital places them accordingly in a distinctly different position from that of the ordinary lay nurse, for they are taught what they should do in cases of difficulty and emergency in the absence of any medical man and during the time that must often intervene before his arrival. The very fact that the most intelligent probationer nurse cannot be made proficient in her course in a less time than two years or more shows that her task is not an easy one. No certificate of training and no authentic diploma or authoritative statement of the person being "a trained nurse" is given in Dublin or in London, or elsewhere in England, under less stringent conditions.

The whole matter is a most important one and has begun to excite great interest in Ireland, not alone among the members of the medical profession, but also among the educated general public. When it is remembered that in no fewer than sixty-seven of the union infirmaries throughout this country the nursing is controlled or carried out by nuns, who, while their unselfish devotion to works of charity is universally recognised, have not received what is understood as hospital training, the importance and possibly far reaching effect of the recent action of the Local Government Board in dissolving the Athlone guardians will be recognised.

BIRMINGHAM.

(FROM OUR OWN CORRESPONDENT.)

Epidemic of Scarlet Fever.

THE increase in the number of scarlet fever cases in the city is a source of much anxiety to the Health Committee. At present there are 457 cases under treatment at the Borough Hospital. It is alleged that some of the cases are sent out too soon, and thus become centres for the further spread of the disease. The difficulties of the committee are being met by utilising the new small-pox hospital at Yardley, where it is proposed to send a number of the scarlet fever patients forthwith. Fortunately, there is not a single case of small-pox in the hospital for the reception of such cases. The medical officer of health, Dr. Hill, believes that the increase is periodic, being due to the accumulation of susceptible material. This is hardly a satisfactory explanation of the present rapid increase. It fails to bring consolation to the sufferers or to the authorities in dealing with so severe an outbreak as the present one.

Periodical Collections for Local Charities.

The committee recently met to make the necessary arrangements for the collections to be made on Hospital Sunday, Oct. 27th. The chairman, Alderman Johnson, stated that this was the thirty-seventh occasion on which the appeal would be made. At the first collection, in 1859, it was pointed out that the sum raised was £5200; this has been the average sum, with little alteration, ever since. With regard to Hospital Saturday, the first collection, in 1873, realised £4705; this has gone on steadily increasing, until last year it reached the large sum of £13,000. Three reasons were adduced to show why the Hospital Sunday collections had not increased in the same proportion: (1) those who furnished the largest contributions on Hospital Sunday were the people who were the regular subscribers to the charities throughout the year; (2) since the movement was founded the number of medical charities had been doubled, and they required support from the very class of people from whom they expected large contributions on Hospital Sunday; and (3) that the resources of the great almsgiving classes were not now what they were in 1859. Profits from trade had decreased, interest from investments was less, and it required an effort on the part of the classes who supported Hospital Sunday to keep up the level of their contributions.

The Lunacy Act.

At the Police-court, on Sept. 30th, Mr. F. R. A. Evans, a surgeon, was summoned for a number of offences under this Act in the alleged wrong treatment of a patient under his care. After evidence had been given the defendant was committed for trial at the Quarter Sessions, bail being allowed, the defendant in £50 and a security of £25.

Medical Men, Coroners, and Death Certificates.

The death of the Rev. Prebendary Finch Smith at Lichfield was the subject of an inquest, at which the deputy coroner, Mr. H. H. Jordan, made some strong remarks. It seems that Prebendary Finch Smith, who was eighty years of age, fell downstairs a few days previously, sustaining an injury to his side, from which he never rallied. A certificate of death was given by his medical attendant. A verdict of "Accidental death" was recorded. The deputy coroner observed "that he felt bound to express his regret that the doctor was not better up in the law than to have given a certificate of death in case of an accident, and that the Deputy Registrar of Births and Deaths had not been better coached in his work than to have accepted such certificate and registered it. Luckily the inspector of police heard of the accident and duly reported it, otherwise there might have been great trouble and annoyance caused to the family." The medical attendant justified his action by the authority of the British Medical Association, to which the deputy coroner took exception as not being a legal authority. It seems that some friction of the same kind had previously existed, hence the disposition to lay down the strict interpretation of the law in its present form in terms which, however much to be criticised, are still the legal ones.

Ambulance Instruction in the Police Force.

The chairman of the Watch Committee recently distributed a number of certificates in these classes and made a presentation to Dr. Holdsworth and Mr. Morrison, divisional surgeons, for the assistance they had rendered in the principles and practice of the work. The assembly was well attended.

The late Dr. Wesley Hayes Thompson of Cradley.

The death of Dr. Thompson at the comparatively early age of forty-five cast a gloom over the district, in which he held an extensive practice. Essentially a self-educated man, he became an apprentice of Dr. Morrow of Cradley Heath, and afterwards went to Anderson's College, Glasgow. In 1871 he took the L.R.C.P. and L.R.C.S. of Edinburgh, and in 1889 the M.D. of Durham. An active and intelligent worker, he soon rose into a prominent position and laboured unceasingly in a large club and colliery practice. His upright conduct and his unassuming manners gained him respect and confidence. He was an earnest advocate of temperance and a devoted member of the Wesleyan body. Some two years ago his health began to fail, and malignant abdominal disease was suspected. Gradually his strength failed, and he passed away on Sept. 26th, leaving a name widely honoured and deservedly esteemed. Mrs. Thompson and seven children mourn their loss, receiving wide and universal sympathy in the district in which Dr. Thompson was born and in which he did so much good and faithful work.

Oct. 2nd.

BRISTOL ROYAL INFIRMARY.—At the half-yearly meeting of the Bristol Royal Infirmary held last week the chairman stated that increased subscriptions were urgently needed as the annual income still fell far short of what was required. A timely and anonymous gift of £1000 had been recently received, but what was wanted was an increase in the regular annual contributions.

SCOTLAND.

(FROM OUR OWN CORRESPONDENTS.)

Inauguration of the New Waterworks for Edinburgh.

FROM time to time the question of an additional water-supply for Edinburgh and district has been referred to in THE LANCET. It has been spoken of for some years, and some persons were most anxious to have the work commenced long ago. Fortunately more prudent counsels asserted themselves, for it has been found that some of the proposed schemes were unsuitable or extremely costly. Now all parties have agreed upon the Tala scheme, the Tala being one of the head waters of the Tweed, and on Saturday last the inauguration of the works connected with this important scheme took place with becoming pomp and suitable ritual. The Lord Provost of Edinburgh, his lady, and the members of the Water Trust were the more prominent actors, but several Members of Parliament and others participated in the proceedings. The religious part of the service was conducted by Mr. S. R. Crockett with impressive solemnity.

The Prosecutions under the Pharmacy Act in Edinburgh.

Last week mention was made of these prosecutions. The acting Sheriff-Substitute has given his decision in two more of the cases. In the case of a photographic chemist the Sheriff, after referring to a circular issued by the respondent announcing that he did not sell poisons unless in wholesale quantities and after reviewing the evidence, held the charge not proven. A further charge of having used and exhibited the name and title of chemist was also found not proven, the Sheriff saying that he did not think the use of the term "photographic chemist" represented him as a chemist in the sense intended by the Act. In the case of one of the scientific instrument makers and technical chemists, the Sheriff found that the sale was a retail transaction, and inflicted a nominal fine of 1*s.* with 2 guineas costs; the second charge was found not proven. Notice of appeal was given on behalf of the Pharmaceutical Society.

Scottish Association for the Medical Education of Women Edinburgh.

The Medical College for Women under the auspices of this society is so prosperous that the quarters they have hitherto occupied in Chambers-street have been found to be too cramped. The association has had the matter under consideration for some time, and when the opportunity offered of obtaining accommodation in Minto House they seized it. The secretary's office is to remain for the present at the old address, but the practical anatomy and other classes are to be held in Minto House. It is understood that the Edinburgh University approves of this change of quarters.

Medical Appointments and Resignations.

The following appointments are intimated at the Western Infirmary, Glasgow: Wm. McLennan, M.B., to be physician to the dispensary; James Carslaw, M.A., M.B., and Hugh Galt, M.B., to be extra-physicians to the dispensary. At the September meeting of the Greenock Parish Council, Wm. S. Cook, B.Sc., M.B., was appointed Assistant Medical Officer to the poorhouse, vice Dr. Holmes, resigned. The Paisley Parish Council have appointed T. Neil Robertson, M.B., C.M., to be resident medical officer at Riccartsbar Asylum, vice Dr. M'Coll, resigned. Dr. Thos. Easton, who has been acting as interim medical officer for the burgh of Stranraer, has sent in his resignation to the town council, as the authorities have neglected to adopt some of his recommendations for dealing with the outbreak of diphtheria from which the town is at present suffering.

Honours to Medical Men.

Dr. John A. Jamieson, Brodick, has been sworn in as an Honorary Sheriff-Substitute for the Island of Arran. Dr. A. Robertson-Fullarton of Kilmichael and Whitefarland, Arran, has been gazetted a Deputy-Lieutenant of the County of Bute.

Fifeshire Medical Association.

The fourteenth annual general meeting of this association was held in Kirkcaldy on Sept. 27th. The President, Dr. Sutherland Mackay, medical officer of health of Kirkcaldy, read a paper on "The Black Death of the Fourteenth Century."

New Infirmary at Helensburgh.

The new building, which has been erected at a cost of about £5000, was formally opened on Sept. 27th by Mr. Alexander Wylie, M.P. for Dumbartonshire. The proceedings attracted much interest in the town, and were witnessed by the majority of the local medical men and leading citizens. Helensburgh is certainly to be congratulated upon the enterprise and public spirit of which the new infirmary is the expression. Until recently there was in the town but a single hospital; in this ordinary medical and surgical cases were treated together with patients suffering from infectious diseases. This unsatisfactory state of matters has now been remedied, and in future the older building, which has been considerably improved, will be used exclusively for the reception of infectious cases.

Glasgow University: Anatomy Fees.

The changes in the arrangements of the Scottish Universities resulting from the action of the Universities Commission have, as was to be expected, not produced universal satisfaction. One of the latest grounds of complaint is in connexion with the fees to be paid for the study of practical anatomy. Under the old system—when fees were paid directly to the Professors—it was the custom of the Professor of Anatomy to allow any student who had paid in fees up to a certain sum to have access to the dissecting-room at any subsequent part of his course. But under the new regulations—each Professor receiving a certain fixed income, and the fees being collected by the University Court—this privilege has been withdrawn, and no student has now the right to make use of the dissecting-room unless he has paid a fee for practical anatomy for the session in which he wishes to study dissections. It is pointed out that such an arrangement will discourage the study of practical anatomy, and will tend to limit men to the minimum of dissection demanded by the Examining Board. It also has the effect of keeping students who have passed their examinations in anatomy away from the dissecting-room, to which it is surely desirable the student should make an occasional visit, during the whole of his medical course. The University Court it is to be hoped will reconsider the matter.

Infectious Diseases (Notification) Act.

The public is only slowly becoming aware of the responsibility imposed upon its members by this Act. Though every possible step has been taken to make its demands known, numbers of parents seem to be quite unaware of its existence. The county council of Renfrew has recently entered upon an "educating" crusade, and by securing the infliction of fines upon parents who neglect to notify the existence of measles in their families are probably adopting the most certain method to enforce a knowledge of the Act and its provisions upon others similarly situated.

Aberdeen University.

The list of honorary degrees to be conferred by the senatus at the inaugural celebrations this month has just been published. Two members of the medical profession are to receive the degree of LL.D. One of these is George Skene Keith, M.A., M.D., who is a graduate in arts of Aberdeen, and studied medicine at Aberdeen, Edinburgh, Pesth, and Paris. He was assistant, and for five years colleague, to the great Sir J. Y. Simpson, and for thirty years afterwards (till 1880) practised his profession in Edinburgh. The second is Sir James Reid, Physician-in-ordinary to the Queen. Sir James Reid graduated M.A. at Aberdeen in 1869, with honours in natural science, being also the Natural Science Prizeman and Town Council Gold Medallist. He then studied medicine at Aberdeen and graduated M.B., C.M., with highest honours in 1872, and subsequently took his M.D. in 1875. He studied at Vienna for two years and then entered on the practice of his profession at Ellon in conjunction with his father. In 1881 he was appointed resident physician to Her Majesty, in 1887 he became physician extraordinary, and in 1889 physician in ordinary. He became a Member of the Royal College of Physicians of London in 1887 and a Fellow in 1892. He was created a Companion of the Bath in 1889, and in June last he was made a Knight Commander of the Order; he also possesses the Red Eagle of Germany (Third Class) and the Saxe-Ernestine Order of Coburg-Gotha (First Class). Among the other recipients of the degree of LL.D. are the Duke of Richmond and Gordon, the Earl of Erroll, the Earl of Southesk, Sir J. Forbes Clark of Lilliepronie, Lord Provost Stuart, &c.—

Digitized by Google

The preliminary examinations for Arts and Medicine are in full swing this week. There are thirty candidates for the Medical preliminary and 220 for the Arts preliminary, a falling off of about twenty since last year. Greek is as popular as ever, but then it still counts more than modern languages for the Bursary competition, which is decided by the same papers as the preliminary examination.—Dean of Guild Walker has presented to the Senatus "Minstrel" Beattie's violoncello, which belonged to the late Mr. James Walker.—The bust of the late Professor Minto is now finished, and will shortly be added to the collection in Marischal College.

The Health of Aberdeen.

The zymotic diseases notified last week were: Measles, 2; scarlet fever, 21; whooping-cough, 25; erysipelas, 3; total, 51; being 6 cases fewer than the preceding week.

Oct. 2nd.

IRELAND.

(FROM OUR OWN CORRESPONDENTS.)

The Nursing in Government Prison Hospitals.

AN inquest was held in the Mountjoy Prison, Dublin, on Sept. 30th, on the body of a convict who had died there rather suddenly from asphyxia caused by some inflammatory disease of the throat. The coroner made some strong comments on the system of nursing at the institution; and the jury added a rider to the verdict "that the nursing system in the prison hospital was defective and ought at once to be improved."

Death under Chloroform.

A death under chloroform has recently occurred at the Coombe Lying-in Hospital, Dublin. The patient, a woman aged forty-eight years, was about to undergo an operation at the hands of Dr. F. Kidd, the master of the hospital, and chloroform was being administered by one of his assistants when a sort of spasm occurred and the woman ceased to breathe. The chloroform, of which less than a drachm had been administered, was stopped at once and every effort made to restore the patient, but without avail. At the inquest, which was held on Sept. 27th, evidence was given by Mr. Kenny, who had made a post-mortem examination, that "the heart was small, flat, and flabby." The jury found "that the deceased died from cardiac syncope while under the influence of chloroform; that the chloroform was administered with all proper precautions and skill; and that no blame was attachable to any official of the hospital."

Outbreak of Typhus Fever near Stewartstown.

A serious outbreak of typhus fever, a disease formerly very common in Ireland, is reported to have occurred among the poor fisher and farmer class on the shores of Lough Neagh, seven miles from Stewartstown in county Tyrone. These people live in small, badly ventilated, and overcrowded houses, and fifteen have been removed to Cookstown Infirmary. All the patients, except two whom the dispensary medical officer did not think it was necessary to compel to enter the fever hospital, have gone there. All the clothes of the patients are to be burned.

The Duties of Medical Officers, Masters, and Matrons in Irish Workhouses.

With reference to the duties of medical officers, masters, and matrons in Irish workhouses, which was raised at a late meeting of the Ballymena board of guardians by their medical officer, Dr. Davison,[1] the matter was again referred to by the master of that union at the weekly meeting on Sept. 28th, and it was decided to ask the Local Government Board to hold a sworn inquiry into the whole subject.

The Kilrea Dispensary.

The Ballymoney guardians recommended recently that the salary of Dr. Lennox, medical officer of the Kilrea dispensary, should be increased by £15 per annum, but after some correspondence the Local Government Board would only sanction an addition of £10, a decision which the guardians regard as very strange.

The Queen's College, Cork.

The annual report of the President, which has been just issued, gives some interesting details with regard to the College. The President states that the total number of students attending the College during the session 1894–5 was 222, the lowest number reached since the year 1876. I find the President of the Belfast Queen's College also reports a diminution in the attendance, which he says was the smallest for twenty years. No doubt the same influences affected both Colleges. The religious denominations of the Cork students were as follows: Roman Catholics, 137; Church of Ireland, 59; Presbyterians, 11; Wesleyans, 12; and other denominations, 5. From the opening of the College in 1849 to the year 1860 the Roman Catholic students slightly exceeded the number of Protestants, but from 1861 to 1872 the Protestants were in a majority except in one or two years. From that year forward, however, the Roman Catholic students have outnumbered, sometimes by more than two to one, all the other denominations. Since 1882 the number of Protestant students has fallen steadily, being now little more than one-half of the number of thirteen years ago. As the medical school forms an important part of the College it would be interesting to analyse the various causes that have produced the results tabulated by the President, but in notes such as these it would be utterly impossible to discuss the subject at all adequately.

Hospital Saturday at Cork.

Last Saturday was Hospital Saturday in Cork, and the weather was all that could be desired. The fair lady collectors, bearing their tinkling tambourines, were bedecked with bewitching summer costumes, and all seemed to augur well for a successful collection, but I regret to say that the street receipts were less than those of last year by about £120. The mayor, who takes a lively interest in the city charities, was much disappointed and publicly stated that the recent "unwarrantable attack on the city hospitals" was one of the most potent influences which militated against the collection. If the mayor's opinion be correct the champion of the Cork clubs can hardly congratulate himself on being instrumental in procuring the diminution of the resources for relieving human suffering and misery. However, I think it only fair to say that in my opinion the mayor attaches an undue amount of importance to the influence possessed by the gentleman to whom he refers, and as an indication in that direction I would mention that the contribution to the Hospital Saturday Fund from the working men of one of the largest firms in the city has been this year almost identically the same as it was last year. Furthermore, it is well known that the committee of management, rightly or wrongly, requested the lady collectors not to press the public, and it was a matter of general comment that the ladies, acting on the instruction they had received, did not exhibit at all the same zeal as had characterised their efforts on previous occasions. The Cork amusement committee gave important aid by providing a very varied entertainment during the afternoon. Amongst the items were musical drill by a detachment of the Royal Irish Fusiliers, and a tug-of-war between sailors from H.M.S. *Warspite* and members of the city police force, in which the constabulary men were the victors.

The Sanitary Condition of Cork.

The Public Health Committee recently appointed a sub-committee to make a general inspection of the city, and as a result of their investigations they have already recommended that in one district several of the houses be closed and demolished, and in the case of other houses that the overcrowding be reduced by permitting only two families to occupy each house. The step taken by the Health Committee is a very important one, and I have no doubt personal inspection by our city fathers will impress them far more than any number of official reports with regard to the absolute necessity for providing decent sanitary habitations for the poor of the city. The medical superintendent officer of health reports that the death-rate for the four weeks ending Aug. 24th was only 15·87 per 1000, the infectious death-rate being 2·06 per 1000. The birth-rate was higher and the death-rate lower than for the corresponding month of last year.

[1] THE LANCET, Sept. 28th, 1895.

INCREASE IN THE SALARY OF A MEDICAL OFFICER. At the last weekly meeting of the Barton Regis (Bristol) board of guardians it was stated that the Local Government Board had approved of the resolution of the guardians to increase the salary of Mr. D. E. Bernard, M.R.C.S., L.R.C.P. Edin., the medical officer to the workhouse, by £25.

RUSSIA.

(FROM OUR OWN CORRESPONDENT.)

Cholera in the Ukraine.

ACCORDING to the latest bulletin from the government of Volhynia the cholera epidemic shows no signs of abating, but, on the contrary, is rapidly increasing, both in that province and in the adjoining one of Podolia. It would, perhaps, be more strictly true to say that the epidemic *was* increasing when the last bulletin was published, now thirteen days ago, and that of its behaviour at the present moment there is no means of judging in the absence of a later announcement. The following are the returns for the periods named:—

—	Cases.	Deaths.
IN VOLHYNIA:		
Between July 23rd and July 29th	1004	322
Between July 30th and Aug. 5th	2025	718
Between Aug. 6th and Aug. 12th	2497	944
Between Aug. 13th and Aug. 19th	3352	1190
IN PODOLIA:		
Between Aug. 9th and Aug. 12th	34	20
Between Aug. 13th and Aug. 19th	67	25

At present cholera is confined to these two governments in European Russia, but it is probably from these border provinces that the infection has spread into Galicia. The disease has for more than a month been present in Tarnopol, and it is also reported from Brody and Rohatyn. In the *starostwo* of Tarnopol the earliest cases occurred at the beginning of August; up to the 11th there were 4 cases with 1 death; in the week ending Aug. 19th there were 6 cases and 3 deaths; in the following week, 17 cases and 9 deaths; and in the week ending Sept. 2nd (14th), 18 cases and 8 deaths. In the far east cholera appears to be diminishing rather than spreading, to judge by the returns from Chi-fu, on the Gulf of Pechili. The Russian Consul in that port telegraphs that in the three weeks between Aug. 13th and Sept. 3rd the deaths from cholera in Chi-fu numbered respectively 20, 14, and 12, adding in his last telegram that the disease had then "lost its epidemic character." Nevertheless, the Russian Government has ordered special precautions to be taken on the Amur and Ussuri rivers to prevent the introduction of cholera infection to the Maritime (Primorskaia) province and the provinces of Amur and Transbaikal.

A Conference on Syphilis.

The Medical Department is making arrangements to hold a conference of representatives of various public health bodies and institutions to consider the question of the spread of syphilis and the best means of combating it. The conference will meet in November, 1896. According to the programme of the conference, which has already been distributed to the local governmental authorities, the discussions will range themselves under the following heads: (1) syphilis in village communities; (2) in towns; (3) in the army and navy; (4) the medical *personnel* required; and (5) the control of prostitutes. The representatives of the St. Petersburg Army Medical Academy at the conference will be Professors Tarnofski, Lebedef, Shideofski, and Sirotinin.

The Serum Treatment of Syphilis.

On the subject of syphilis Dr. Viéviorovski published in a recent number of the *Vratch* (No. 34) a preliminary note on the treatment of five cases of syphilis by the injection of serum from the blood of patients in the tertiary stage of the same disease. The results were very satisfactory. There was subjective improvement in all the patients; there was also an unusually rapid healing of primary sores; roseola and mucous and hypertrophic papules in the mouth and round the anus disappeared after from two to four injections. The continuance of the treatment after the disappearance of symptoms did not, however, prevent their recurrence; and it was noted that in such cases a second course of injections was not followed by such rapid improvement as the first course. The number of injections given in each case was from twenty to twenty-three, an average of 10 c.cm. of serum being given in each injection. The experiments were carried out in the Military Hospital in Moscow. Full details are promised in a later communication.

The New Pirogoff Museum.

The foundation-stone of the new Pirogoff Museum of Anatomy and Surgery was laid on Thursday last. The construction of such a museum was suggested by Professor Ratimof, who is now President of the Pirogoff Chirurgical Society. The scheme was well seconded; the Government provided 30,000 roubles towards the purchase and reconstruction of a building to contain the museum, and a sum of 60,000 roubles bequeathed to the society by the late Countess Musin-Pushkin, to be expended on some memorial to the great Russian surgeon, has been put aside as an endowment of the new museum. The society has purchased a building, used as a Government store since the time of the Empress Anna, appropriately situated on the banks of the Neva not far from the Army Medical Academy and the large military hospital named after Sir James Wylie. The museum will be arranged on the lines of the Hunter collection in Lincoln's-inn-fields and that of Dupuytren in Paris. A curious incident occurred during the digging operations in connexion with the reconstruction of the building. A large quantity of human bones were found in the earth underneath the foundations. One theory in explanation of their presence is that the ground was formerly used as a cemetery; a second suggestion is that the bones are the remains of the innumerable victims who died by the axe or the halter in Peter the Great's time. Both suggestions require confirmation; there is said to be some reason for believing that the bones were deposited after the building, which dates from 1732, was constructed.

St. Petersburg, Sept. 16th (28th).

THE DIFFUSION OF SMALL-POX.—The diminution of small-pox notifications in London recorded in our last issue has continued during the week ended with last Saturday, the actual cases and admissions to hospital, as well as the number of patients remaining under treatment, being below the totals of the preceding week. Last week 21 patients were removed to the hospitals of the Metropolitan Asylums Board or to the Highgate Small-pox Hospital, against 25, 42, and 23 in the three previous weeks, and on Saturday last the number of patients still under isolation treatment had fallen to 234—a total which has been steadily diminishing for many weeks past. There were again 2 deaths from the disease registered in London last week, 1 belonging to Hackney and the other to Lambeth, both in unvaccinated infants. Some small amount of the disease has recently been recorded in the south-western counties, where active steps are being taken to prevent its spreading. A few cases occurred in Lancashire last week, of which 4 were in Manchester, but no death was reported. In Dublin during the week ended Sept. 21st 5 cases were admitted to hospital, comparing with 4 and 9 in the two preceding weeks. The number of patients remaining under treatment was 22, as compared with 15, 13, and 18 on the three previous Saturdays. There was only 1 death, the patient being a child five years of age who had no medical attendance, and was stated to have been vaccinated in infancy.

PRELIMINARY TRAINING FOR NURSE PROBATIONERS.—A new departure in the training of nurses has been undertaken by the authorities of the London Hospital, and was brought under the notice of our readers in THE LANCET of May 11th last. A suitable building, called Tredegar House, has been acquired in the Bow-road, at some distance from the hospital, as a residence and preliminary training home for twenty young women desirous of becoming probationers. These pupil-probationers will receive instruction in the household duties, such as sweeping, dusting, &c., which they will subsequently have to perform in the wards, and they are expected to become proficient in sick-room cookery, bandaging, and such details of practical nursing as can be conveniently taught. They will also attend lectures and classes in elementary physiology, anatomy, and hygiene. After six weeks' preliminary training the pupils who are deemed suitable will be transferred to the hospital for a month's trial, and the three years' engagement to the hospital will count from the commencement of work in the wards.

Obituary.

LOUIS PASTEUR.

OUR PARIS CORRESPONDENT writes:—The daily papers will have already informed the readers of THE LANCET of the death of Louis Pasteur. These same lay journals will, moreover, have supplied them with details of his private life and scientific career which I may, unconsciously, repeat in this notice. But the Paris representative of an organ like THE LANCET cannot be silent on such a momentous and painful occasion, and I therefore proceed to communicate to its readers the impressions reflected in my mind by the disappearance of this great man. Pasteur died at 5 P.M. on Saturday, Sept. 28th, at Garches, in that part of the domain of Villeneuve-l'Étang placed at his disposal for the study of rabies by the municipality of Paris. The house occupied by M. Pasteur and his family is extremely modest in extent and in style. It formerly sheltered the piquet of the Cent Gardes attached to the Imperial château of Garches. The château itself was destroyed after the Franco-Prussian War, but the floor beneath that in which M. Pasteur breathed his last is still occupied by horses—not, indeed, troop horses, as in old times, but horses vaccinated against diphtheria, and supplying the precious fluid antitoxin. In 1868 M. Pasteur had an attack of cerebral hæmorrhage which left behind it permanent hemiplegia of the left side. It is a remarkable circumstance that such a grave pathological occurrence did not incapacitate him from pursuing his onward scientific path. I am sorry to say that ill-health was coincident in its onset with the virulent attacks made on him by one of our own body—the late Professor Peter—when in 1886 his earliest anti-rabic discoveries were communicated to the scientific world. The annoyance caused by these attacks brought on insomnia and palpitations, culminating in a condition of heart failure, which necessitated a sojourn during the winter of 1887 in M. Bischoffsheim's villa at Bordighiera. An earthquake compelled a premature return to Paris, symptoms of heart failure reappeared occasionally, and albuminuria was superadded. Several times, especially in 1892, disquieting attacks of uræmia were a source of anxiety to his *entourage*. On Nov. 1st of last year a fresh attack kept him in bed for several months at his residence in the Institut Pasteur. The healthy surroundings of Garches contributed greatly to re-establish his strength, but the remarkable heat of the summer of the present year proved too much for him, and uræmic symptoms reappeared. The treatment prescribed by his medical attendants, Drs. Chantemesse and Metchnikof, had the desired effect until Wednesday, Sept. 18th, when a recurrence of uræmia occurred. Temporary improvement was followed on Sunday, the 22nd, by a relapse. His pupils of the Pasteur Institute nursed him in relays, but on the morning of Thursday, the 26th, the situation became so alarming that messages were despatched to his intimate friends, who — Professor Granche amongst the number — hastened to his bedside. Dr. Roux, who was in the department of Charente, reached Garches on Saturday morning, when the illustrious sufferer was almost comatose and a prey to intense uræmic dyspnœa. About 5 P.M. he died, surrounded by his devoted wife, his daughter (Mme. Vallery-Radot) and her husband, his nephew (Maurice Loir) and his mother (M. Pasteur's sister), Drs. Chantemesse and Metchnikof, and M. Nocard. He had not spoken a word since 4 A.M., when, Mme. Pasteur and his daughter asking if he felt any pain, he feebly answered "Oui." This was the last word he uttered. All being over, his devoted pupils, Drs. Chantemesse and Metchnikof, performed his last toilette on earth, Mme. Pasteur placed a scarf around his neck, the arms were crossed over the breast, and a crucifix fixed between his hands. M. Pasteur's nephew, Maurice Loir, was authorised to make a sketch in crayons of the body, but no photograph was allowed to be taken. The Curé de Garches and a Dominican Father visited the deceased on the day of his death. It is said that M. Pasteur was quite cognisant for a long time before the fatal *dénouement* of the danger he was in. Some time ago, embracing his little grandchildren, he suddenly broke down, and, in explanation of his emotion, said, "C'est parce que je vais vous quitter, mes enfants." His only son, M. Jean-Baptiste Pasteur, First Secretary at the French Embassy at Madrid, reached Garches two hours too late to see his father alive. The Ministry *au complet* inscribed their names on Sunday in the register installed at the entrance of the park of Villeneuve l'Étang, as also did numerous deputies and senators as well as members of the Institut. M. Poincaré, Minister of Public Instruction, announced to the widow and son of the deceased the intention of the Government to sanction a national funeral and interment in the Panthéon. Mme. Pasteur, while agreeing to a State ceremony, informed the Minister that her illustrious husband had always expressed a desire to be buried close to his laboratory in the Rue Dutot (Institut Pasteur). After the departure of the Ministers the *chefs de service* of the Institut Pasteur proceeded to embalm the body, and, Mme. Pasteur having been induced to take needed rest, the body was watched by Drs. Roux, Duclaux, and Prevot.

LOUIS PASTEUR.

The portrait is reproduced by kind permission of Messrs. Macmillan and Co., the proprietors of "Nature."

Born at Dôle (Jura), his father being a poor working tanner, Louis Pasteur owes his pre-eminence entirely to his own intelligence and pertinacity. Even when Louis was only two years old his father entertained hopes of future greatness for him. M. Pasteur was fond of recalling an oft-repeated desire thus expressed by his father: "Ah! si tu pouvais devenir un jour professeur, et professeur au collège d'Arbois, je serais l'homme le plus heureux de la terre." What would the good tanner have said if he had known that, fifty-eight years later, in the presence of his son now covered with glory, a tablet would be placed on the walls of the modest house in the Rue des Tanneurs bearing the following inscription in letters of gold:—

Ici est né Louis Pasteur
le 27 Décembre, 1822.

In 1825 the family left Dôle for Arbois, a small town (in the same department) of (now) 5000 inhabitants. Here, in the small tannery bought by his father, Louis passed his early years. In due course he was sent as a day-scholar to the *collège communal*. He, the youngest of all the scholars, was so proud to pass the portals of this institution that he arrived with an armful of huge dictionaries of which he was in no need whatever. His father utilised his short leisure in helping Louis with his lessons.

Digitized by Google

The little one was, it appears, not always over-anxious to join his father on these occasions, preferring to engage in fishing or in taking a pastel drawing of a neighbour's lineaments. A dozen of these portraits still exist in different houses at Arbois, and their excellence is so striking for a boy aged thirteen that a short time ago an old *Arboisienne* exclaimed: "Quel dommage qu'il se soit enfoncé dans un tas de chimie; il a manqué sa vocation, il serait arrivé à se faire une réputation de peintre." But Louis soon showed the grit lying hidden in his character, and when, applying himself seriously to work, he easily distanced all his companions the principal of the college uttered a prophecy destined to be amply realised: "Il ira loin." The Arbois College being minus a *Professeur de philosophie* young Pasteur left for Besançon, where, after one year's study, he took his degree of *Bachelier ès Lettres*, and was immediately appointed an assistant master. His leisure time was devoted to attending lectures on higher mathematics in view of admission to the examination in science at the École Normale of Paris. His bent towards the study of chemistry was at this period of his existence but too evident from the embarrassing questions he was wont to put before the entire class to his old professor, Darlay, who, poor man, was at last constrained to say that it was for him to ask Pasteur for information instead of the reverse. At the examination for admission into the École Normale, Pasteur was No. 14 on the list. Although admissible, being dissatisfied with his place on the list he resumed his preparation, with the result that the following year he was classed fourth. Now, with Dumas at the Sorbonne and Balard (the discoverer of bromine) at the École Normale, he could give free play to his chemical curiosity. Chemical manipulations were all he cared for, all he thought about, and when his comrades would employ their spare moments in recreation he would shut himself in with his beloved flasks and crucibles in order to satisfy that craving for light that was destined to lead him to such marvellous and beneficent discoveries. Now came his first discovery. His delight was so overpowering that he rushed out of the laboratory, and meeting the *préparateur* of the physics lectures he fell on his neck, exclaiming: "Mon cher Monsieur Bertrand, je viens de faire une grande découverte. J'ai séparé le paratartrate double de soude et d'ammoniaque en deux sels de dissymétrie inverse et d'action inverse sur le plan de polarisation. Le sel droit est de tout point identique au tartrate droit. J'en suis si heureux que j'éprouve un tremblement nerveux qui m'empêche de remettre de nouveau l'œil à l'appareil de polarisation. Allons au Luxembourg, je vous expliquerai cela." This discovery created a profound sensation at the Académie des Sciences. Biot, appointed by his colleagues, amongst whom were numbered Arago, Dumas, and Sénarmont, exacted of Pasteur the verification of every point in his discovery. In September, 1846, he was appointed *agrégé des sciences physiques*, but he continued his connexion with the École Normale until 1848 in the capacity of *préparateur* in chemistry. In 1847 he took his degree of D.Sc., and the following year he undertook the duties of Professor of Physics at the Dijon Lycée. Three months later, however, he was called to the temporary occupation of the chair of Chemistry at the Faculty of Sciences of Strassburg, his appointment being rendered definitive in 1852. Towards the end of 1854 Pasteur, as Dean, was entrusted with the organisation of the newly created Faculty of Sciences of Lille. In 1857 he returned to Paris as the scientific director of his old school, the École Normale. He had then been married for seven years, having espoused during the tenure of the professorship of chemistry at Strassburg the daughter of M. Laurent, the Rector of the Strassburg Academy. In 1852 their only son, Jean-Baptiste, was born. The other children, four daughters, were all born in the Rue d'Ulm, Paris, where Pasteur laboured until the Institut Pasteur was built. Three daughters are dead, the surviving one being the above-mentioned Madame Vallery-Radot. In December, 1862, M. Pasteur was appointed Professor of Geology, Chemistry, and Physics at the École des Beaux Arts, and also member of the Institute. A few years later he became the permanent secretary of the Institute; this post he retained until 1889, when he assumed the direction of the Institut Pasteur. In 1881 he was elected an Immortal, taking the *fauteuil* of Littré at the Académie Française. Amongst the other honours accorded to him may be mentioned the Rumford Medal, conferred in 1856 by our Royal Society for his researches on the polarisation of light with hemihedrism of crystals. The Jecker Prize was awarded him in 1861 for his chemical labours. In April, 1874, at the instance of a commission entrusted with the examination of his works, the Minister of Public Instruction proposed to the National Assembly that a national life pension of 20,000 francs (£800) a year should be given him. This was adopted. Since 1881 M. Pasteur was Grand Cross of the Legion of Honour. On Dec. 27th, 1892, on the occasion of his seventieth birthday, an immense ovation awaited him at the Sorbonne, the late regretted President Carnot, all the Ministers and ambassadors, the members of the French Institute, and delegates from every known university and scientific society in the world being present to salute him. Pasteur entered the crowded amphitheatre leaning on the arm of M. Carnot, and I remember that on that occasion I sent THE LANCET a *résumé* of the admirable speech made by M. Dupuy, then Minister of Public Instruction. Sir Joseph Lister—that practical mind which, with the instinct of genius, first realised the vast importance of Pasteur's bacteriological discoveries and deductions—then delivered a speech which I transcribe *in extenso*:—

"Vraiment," dit-il, "il n'existe dans le monde entier aucun individuel auquel doivent plus qu'à vous les sciences médicales. Vos recherches sur les fermentations ont jeté un rayon puissant qui a illuminé les ténèbres funestes de la chirurgie et a changé le traitement des plaies d'une affaire d'empirisme incertain et trop souvent désastreux en un art scientifique sûrement bienfaisant. Grâce à vous, la chirurgie a subi une révolution complète qui l'a dépouillée de ses erreurs et a élargi presque sans limite son pouvoir efficace. La médecine ne doit pas moins que la chirurgie à vos études profondes et philosophiques. Vous avez levé le voile qui avait couvert pendant des siècles les maladies infectieuses. Vous avez démontré leur nature microbienne; grâce à votre initiative, et dans beaucoup de cas à vos propres travaux spéciaux, il y a déjà une foule de ces desordres pernicieux dont nous connaissons complètement les causes. Cette connaissance a déjà perfectionné d'une façon surprenante le diagnostic de ces fléaux du genre humain et a indiqué la route qu'il faut suivre pour leur traitement prophylactique et curatif. L'originalité de vos travaux sur la rage était si frappante que, à part quelques ignorants, tout le monde reconnait maintenant la grandeur de ce que vous avez achevé contre cette maladie terrible. Vous avez fourni un diagnostic qui dissipe à coup sûr les angoisses d'incertitudes qui hantaient autrefois celui qui avait été mordu par un chien sain soupçonné de la rage. Rien que cela aurait suffi pour vous assurer la gratitude éternelle de l'humanite. Mais par votre système merveilleux d'inoculations antirabiques vous avez su poursuivre le poison après son entrée dans le système et l'y vaincre."

M. Pasteur's emotion was so great that the reply he had prepared had to be read by his son. After a touching reference to his master, Claude Bernard, his discourse ended with the following profession of faith:—

"Je crois invinciblement que la science et la paix triompheront de l'ignorance et de la guerre; que les peuples s'entendront non pour détruire mais pour édifier, et que l'avenir appartiendra à ceux qui auront le plus fait pour l'humanité souffrante. Jeunes gens, jeunes gens, confiez-vous à ces méthodes sûres, puissantes, dont nous ne connaissons encore que les premiers secrets. Et tous, quelle que soit votre carrière, ne vous laissez pas atteindre par le scepticisme dénigrant et stérile, ne vous laissez pas décourager par les tristesses de certaines heures qui passent sur une nation. Vivez dans la paix sereine des laboratoires et des bibliothèques. Dites-vous d'abord: Qu'ai-je fait pour mon instruction? Puis, à mesure que vous avancerez: Qu'ai-je fait pour mon pays? jusqu'au moment où vous aurez peut-être cet immense bonheur de penser que vous avez contribué en quelque chose au progrès et au bien de l'humanité. Mais, que les efforts soient plus ou moins favorisés par la vie, il faut, quand on approche du grand but, être en droit de se dire: 'J'ai fait ce que j'ai pu.'"

M. Pasteur's last official speech was delivered on the occasion of the visit made on Oct. 24th, 1894, to the Institut Pasteur by President Casimir-Perier for the purpose of handing to Dr. Roux the insignia of Commander of the Legion of Honour. Some days before the Kiel *fêtes* Pasteur, who had been approached with the view of his acceptance of the Prussian order "Pour le Mérite," and who had refused the proffered honour, wrote to the Comte Féry d'Esclands in connexion with a proposed patriotic manifestation at the Pasteur Institute in these terms:—

"CHER MONSIEUR FÉRY D'ESCLANDS,—Je suis extrêmement touché des sentiments que vous avez exprimés; mais laissez, je vous prie, à ce que j'ai fait en toute simplicité, un caractère très simple. Je ne veux ni manifestation ni souscription.—Veuillez agreer, &c.,

"L. PASTEUR."

It is, perhaps, not generally known that, in consequence of the bombardment in 1871 of the Museum and the Jardin des Plantes by the Prussians, M. Pasteur returned the diploma of membership awarded by the Bonn University. It is said, on the authority of the *Figaro*, that the astounding reply ran as follows: "L'Université de Bonn adresse à M. Pasteur l'expression de son plus profond mépris." The funeral of M. Pasteur is fixed for Saturday next. A service will be held at Notre-Dame by special permission of Cardinal Richard, the Archbishop. The body will probably remain.

Digitized by Google

in the Cathedral mortuary until its transference to its last resting-place, the Pasteur Institute, on Oct. 23rd, which is the centenary of the foundation of the Institut de France. On Saturday only one speech will be delivered—that by M. Poincaré, Minister of Public Instruction, as representing the Government. The body will be brought to-day (Oct. 1st) to the Institut Pasteur, where the flag flies half-mast high, and the Administration des Pompes-Funèbres has already begun to hang draperies on the deceased's house situated in the grounds. Permission to bury a body in a private house has not until now been given for the last twenty-five years. Telegrams of condolence continue to pour into Garches, the senders belonging to all classes of society. Yesterday the public was allowed to defile before the remains, and a touching visit was paid to the *chambre mortuaire* by the *personnel* of the Institut Pasteur. I thought that the foregoing lengthy personal details might be deemed worthy of perusal by the readers of THE LANCET. I can only conclude by giving expression to a belief shared by everyone who has studied his life-work—viz., that in Louis Pasteur humanity has lost its greatest benefactor.

The death of Louis Pasteur has removed from among us one of the most remarkable figures in the scientific world, an enthusiast in the pursuit of truth for its own sake, who yet received his meed of honour at home and abroad, and was not without more substantial rewards. His career affords a striking illustration of the influence of apparently trifling incidents in directing the future course of a great man's life, and of the far-reaching results that may proceed from the discoveries of science even when the immediate success aimed at has been achieved, results beside which the latter sinks into insignificance. Little did he think that his researches, undertaken at the instance and for the benefit of brewers and wine-growers, would suggest the antiseptic and aseptic methods of treatment which, perfected by Lister and Semmelweiss, have been the means of saving thousands of lives annually and of rendering practicable and safe many operations which had previously been utterly unjustifiable, or that his investigations into the diseases of silkworms would, after restoring prosperity to his country, not only give a new and fruitful direction to his own biological studies, but lead to results in the hands of others trained in pathological methods which have within a quarter of a century revolutionised the whole science of communicable disease, opened up boundless fields of research, and give promise in the future of methods of prevention and cure in the strictest sense of the word which scarcely a dozen years ago would have appeared as the wildest of dreams. Yet so it has been with all he undertook; the successes he achieved, and the conclusions at which he arrived, have suggested to others lines of research and fields of discovery the borders only of which have as yet been explored and our knowledge of which is being extended every year, nay, almost every month, until the mind is lost in the contemplation of what may yet be revealed. About the year 1847 an incident, trivial in itself, turned his attention from pure and chemical physics to those biological studies on which his fame was to be built. A German firm of manufacturing chemists having observed the proneness to fermentation of solutions of impure commercial tartrate of lime, Pasteur, experimenting on pure ammonium tartrate, found that the addition of a small quantity of albumin to a solution of the salt was followed by fermentation, accompanied by the appearances of minute cells, which he showed to be the cause of the change. Thenceforth he devoted his energies almost exclusively to the study of fermentation. Caignard de la Tour had some years previously proved the torula to be a living organism, and the efficient cause of alcoholic fermentation in beer, and Schwann had shown all putrefaction to be caused in like manner by microscopic fungoid organisms. These discoveries were extended by Pasteur, who studied the phenomena of fermentation, alcoholic, butyric, acetic, and lactic, under all possible conditions of temperature and in the presence and the absence of air. He showed that each was due to a specific organism, and that different organisms were concerned in the alcoholic fermentation of wine, and of beer, and of beer brewed in the English and the German methods, as well as in the irregular and by-fermentations to which all, especially British beers, are liable. He distinguished between aerobes and anaerobes, or those which thrive best in the presence or absence respectively of air. Apparently spontaneous fermentations were, he maintained, set up, as was putrefaction, by germs floating in the air, almost ubiquitous though far more sparsely distributed in the higher regions of the atmosphere, but even there occurring in "clouds," so that fermentable liquids might be exposed at different times with different results. These views were warmly opposed by Pouchet, who adhered to the old notion of the spontaneous generation of the lowest forms of life from dead organic matter, abiogenesis as he called it; but Pasteur, supported by Professor Tyndall in this country, successfully exposed the omissions of necessary precautions which falsified Pouchet's observations. Access of air was in itself insufficient to set up fermentation if the germs it contained were destroyed by heat or caustic solutions, or even arrested by a layer of cotton-wool previously sterilised by baking. The juice taken from the interior of the grapes would not ferment if it were not allowed to come in contact with the skins to which the germs adhered, nor would the "must" from grapes crushed with their skins if they had been enveloped in sterilised wool throughout the whole period of their growth and when gathered were taken away from the vineyard, a fact of which he gave a public demonstration. The same he showed to be true of putrefaction, and thus laid the basis of the possibilities of antiseptic surgery. In 1865 he was invited by his old friend and former teacher, Dumas, to turn his attention to the prevention of the pébrine, a parasitic disease of the silkworm, the ravages of which had in twelve years reduced the annual revenue to the State from 130,000,000 to 8,000,000 francs, and threatened the utter destruction of an important industry, the prize of half a million francs offered by the Government having failed to elicit any efficient remedy. In 1859 Vittadiani and Cornalia had proved the connexion of the disease with the mobile corpuscles that previous observers had detected in the tissues of the worm and in the eggs, and shown how the infected eggs might be distinguished from the healthy. Pasteur soon found that the parasites once introduced persisted in every succeeding phase of the animal's development and were perpetuated through subsequent generations; that the worms by wounding others with the claws of their anterior limbs infected, or were infected by, one another; that the disease was spread without actual contact by their excreta and by dust diffused in the air; and that the only hope lay in rearing a fresh strain from healthy and, if need be, imported eggs, all infected worms and things capable of retaining infection having been meanwhile destroyed. Acting on this advice the growers succeeded in banishing the plague, and in a few years prosperity was restored. From this time to the end of his career Pasteur devoted his energies to the study of the communicable diseases of the higher animals, as anthrax, swine fever, the so-called fowl cholera, and others—identifying and cultivating artificially the specific microbes of each. Anthrax, charbon, or splenic fever as it is variously called, constantly present in Russia and Asia Minor, extended its ravages from time to time to other countries, and attacking cattle, sheep, and occasionally man, especially persons who inoculated themselves in the handling of hides or wool. He found that by cultivating the microbes in artificial media under conditions more or less unfavourable their virulence could be progressively reduced, and that inoculations with these "attenuated" cultures, while rarely inducing more than a slight febrile disturbance, conferred on the animal an immunity from subsequent infection, scarcely less than that which was enjoyed by the few that survived attacks of the natural disease. In his admiration of Jenner, whose follower he claimed to be, he called his operations "vaccinations" and the attenuated virus "vaccines," though differing in some essential points, and far more closely resembling the former practice of inoculation and open to like objections and dangers. We readily admit that thousands of cattle were thus rendered insusceptible, but from the impossibility of attaining uniformity in the strength of the fluids the inoculations frequently caused the death of the animals to be protected, or failed to give the desired immunity, and the practice has fallen very generally into disuse. Pasteur's last work was the search after a means for preventing the development of hydrophobia in man through the bite of rabid dogs or other animals. Here no microbe has as yet been discovered, and he thus laboured under the difficulty of not knowing the nature of the poison with which he had to deal. Since, however, it had an especial affinity for and was concentrated in the nervous centres he was under the necessity of employing extracts or

Digitized by Google

emulsions of nerve substances as he otherwise would have used culture fluids. His procedure consists in subdural inoculation of rabbits, in whom the disease always assumes the paralytic and painless type. The cords of these animals, after having been subjected to certain treatment, are used for the inoculation of others until a virus is obtained of the desired strength. In man the subcutaneous method is employed by means of a series of inoculations commencing with the weakest fluid and ending with one which, if it had been used at first, would have inevitably proved fatal. For this Pasteur has been attacked and vilified, and his statistics impunged by a certain class of humanitarians and by the anti-vivisectionists; but neither prejudice nor incredulity can disprove the fact that, with a few unavoidable failures due to easily recognised circumstances, numbers of dogs have been rendered absolutely resistant and insusceptible, and that the percentage of persons bitten, often severely, by dogs and wolves as to whose rabid state no doubt could be entertained, in whom no symptoms of hydrophobia have supervened vastly exceeds that which might have been expected under any other conditions or treatment. We should be the last to disparage the immediate results of Pasteur's discoveries, but perhaps their greatest value has been, and will ever be, found in the indications they have afforded to other investigators for opening up new fields and following further lines of research. Lister's antiseptic surgery and Koch's pure cultures are already old, but Behring's antitoxins possess incalculable advantages over attenuated toxines in culture fluids of indeterminate strength, and Tizzoni appears to have succeeded in substituting a similar product for the antirabic inoculations of Pasteur. Though his patriotism led him to refuse or return every honour proffered by the German Government and universities, it must be said that to his credit the preparation of Behring's diphtheritic antitoxin was promptly taken up at the Pasteur Institute by himself and his colleague, Dr. Roux.

Pasteur's engrossing subject of study, however, was undoubtedly chemistry, and by his death chemical science has lost one of its most ardent and successful students. Just three years after joining the École Normale he was appointed Assistant Professor of Physical Science, and in another two years he took his degree as Doctor. Later he filled the chair of Professor of Physics at Dijon, which, however, was resigned after a few months for the chair of Chemistry at Strassburg. Still another appointment he held—at Lille—before he returned to the École Normale as Director of Scientific Studies. In the meantime he had been conducting his famous bio-chemical researches and making experimental study of the phenomena of fermentation. It was at this time that Pasteur proved the presence of germs in the air by an original and ingenious experiment. He placed gun-cotton, which has the texture and appearance of ordinary cotton-wool, in a glass tube through which air was drawn for some time. The plug of gun-cotton was then withdrawn and dissolved in a mixture of ether and alcohol. A residue was thus obtained which proved to contain the seeds of organic life, as was revealed by microscopical examination and by their capacity to develop into organisms, moulds, &c. under suitable conditions. Subsequently Pasteur confirmed the correctness of the observations made previously by Latour, Schwann, and Kützing that yeast consists of low organisms which are self-propagating. The great Liebig, it is interesting to recall, opposed this vitalistic theory; he did not dispute the organised nature of yeast, but would not acknowledge that the latter itself gave rise to fermentation through its life processes. He assumed, on the other hand, the presence in yeast of an albuminous ferment which on the death of the former brought about the decomposition of the sugar into alcohol and carbonic acid. Pasteur showed that this change was not so simple as was represented in the mere splitting up of sugar into alcohol and carbonic acid, but that there were other important substances produced, as, for example, succinic acid and glycerine. This interesting formation by low organisms of an organic acid from a carbohydrate was doubtless the sign-post which led Pasteur to the investigation of the optical properties of tartaric and racemic acids. His beautiful researches on these substances have proved to be of the utmost importance, since they established the relations existing between optical activity and crystalline form, and have thrown considerable light upon the architecture of molecules. It was the foundation of stereo-chemistry or of the chemistry which treats of the position of the atoms in a molecule. When we reflect that it is the position of the atoms in the molecule which determines the properties of the substance the importance of this discovery is clear, but probably not yet appreciated to the full, inasmuch as a more extended knowledge of the constitution, and therefore of the properties, of bodies is calculated to place pharmacology and therapeutics on a sounder and more satisfactory basis. Pasteur showed that racemic acid was the double inactive form of tartaric acid, and is simply composed of equal quantities of dextro- (turning the plane of polarised light to the right hand) and of lævo- (polarising to the left hand) tartaric acid. Thus racemic acid is inactive by external compensation. By methods which are now well known Pasteur proved this by separating racemic acid into two tartaric acids optically opposite in character. Moreover, racemic acid is recovered when a solution of equal quantities of the oppositely active modification is carefully evaporated to dryness. The components of racemic acid could also be obtained, Pasteur found, by the selective action of living organisms (Penicillium glaucum). Pasteur suggested as a possible cause of these optical differences a screw-formed arrangement of the molecules. Our knowledge on these matters has since advanced by leaps and bounds, and this memorable discovery of Pasteur has since opened an almost limitless field of exploration for the chemist. Putting on one side, however, the question as to how far these researches may prove to be of direct benefit to mankind, there remains yet to be mentioned the untold good which followed the practical application of many of Pasteur's discoveries. Of national importance, for example, was the success with which he combated the "diseases"—for so he accounted them—of wine, beer, and vinegar. By the application of his studies on fermentation he was able—to take one example—to restore to his country an annual loss of wine represented by one-fourth of the total quantity produced, or amounting in value to some five millions sterling. For this and similarly great benefits conferred upon national industries he was awarded 12,000 francs by the Society of Encouragement of Paris, and an annuity of the same value by the National Assembly of France, which was supplemented further by a full retiring pension from his professorship at the Sorbonne in 1875—a post he had occupied since 1867—thus enabling him to carry on his scientific and experimental studies without the hindrances of professorial engagements. Space precludes us from enumerating several other splendid examples of the outcome of his chemical and bio-chemical researches which became of more than national importance. We may be content with mentioning his discovery of a remedy for the parasitic disease of silkworms, by which one of the most important industries of France was saved from, as it had been again and again threatened with, complete ruin; his success in the treatment of "cholera" among poultry and goitre among cattle; and, lastly, the measures which he suggested, and which were attended with excellent results, for the prevention of the ravages of the phylloxera, the worst enemy of the vineyards. Chemistry has indeed lost a faithful student and the community at large a noble servant whose keen scientific insight was devoted almost entirely to their interests and well-being.

Sir Joseph Lister has favoured us with the following remarks, which will be read with interest:—"It would be impossible in the short time at my disposal to refer even cursorily to the brilliant and far-reaching discoveries of Pasteur, which have revolutionised both medicine and surgery. I must content myself with a few words regarding his personal characteristics. His acuteness as an investigator in seizing upon essential points and his wonderful lucidity of judgment were only equalled by the patience with which he pursued what he termed *la méthode expérimentale;* and his enthusiasm was always tempered by dispassionate caution. In doing battle with the fallacious doctrine of spontaneous generation he was a keen controversialist, but his utterances were always characterised by transparent truthfulness. His rare modesty and entire freedom from affectation made intercourse with him easy and delightful. Anyone who reads the account he gave in the *Comptes Rendus* of the case of the little boy on whom he first ventured to employ antirabic injections in the human subject will see clear indications of another feature of his character—loving tenderness of heart. His splendid early work in physics and chemistry proved, indeed, how dearly he loved pure science for its own sake; yet it was undoubtedly the great joy of his later

Digitized by Google

researches that they directly promoted the good of mankind. In Pasteur the world has lost a personality as beautiful as it was great."

PROFESSOR ADOLF VON BARDELEBEN.

THE medical faculty of Berlin has lost one of its oldest and most popular members. On Sept. 25th there died Professor Adolf von Bardeleben, Ordinary Professor of Surgery, chief surgeon of the Charité, and hospital and general surgeon of the army medical staff. Although he had reached an age when the majority of medical men retire from work, he performed his manifold and responsible functions till his death; and whoever had met him in the hospital wards, in the lecture-room, or at the committee meeting of the German Surgical Association might well have believed that he would continue to do so for a long time. Bardeleben's surgical career extended over more than half a century: he began his work at the time when anæsthetics were first used, and closed it when surgery dares successfully to attack every organ of the human body. Although not personally connected with any striking inventions or methods, he was always ready to avail himself of new methods in surgery. When more than fifty years old, at a period of life when a change of habits is seldom seen in medical men, he, with the late Professor Volkmann, made the antiseptic method first known to the profession of his country, and in spite of the scepticism which Sir Joseph Lister's work met with in the beginning he was one of his most ardent champions in Germany. He had to contend against the administration of his hospital, who believed the new method to be too expensive; and he is said to have made personal pecuniary sacrifices in order to supply the necessary dressing materials for his patients. He substituted in Lister's dressing chloride of zinc for carbolic acid, and employed cheap gauze instead of the rather expensive mull. At last, within a few years he saw the great invention of Lister introduced wherever surgical work was done. The number of his literary publications was but small; he did not care to make a monograph of every uncommon case or to publish every little modification in operations as a new method—to be called, of course, after him. His principal work was the translation of Vidal's Surgical Handbook, which he revised with every new edition, so that it became the standard work on German surgery for more than thirty years. There were, indeed, few men more able to perform such a work than Bardeleben; he not only was fully acquainted with modern surgery, but he also had an intimate knowledge of the history of our science. He had read the works of the old surgeons, and in his lectures liked to cite passages from them in order to show his pupils the enormous progress of medicine. The extent of his knowledge may be illustrated by the fact that he once acted as Lecturer on Zoology in the place of his friend the late Professor Vogt, who had been elected member of the Parliament of Frankfort. We have called him one of the most popular medical professors, and indeed there are few in Berlin who were so universally liked. Although the construction of his hospital did not in any way meet the demands of modern surgical education he had a numerous and most attentive audience overcrowding the small lecture-room to which he was limited. The morning visits especially were attentively followed by the students, as he was one of the few professors in Berlin who liked to be accompanied by his pupils in the hospital wards and to demonstrate the cases. But he was not only venerated by the students, but also by the patients, with whom he was exceedingly gentle and sympathetic. Being in a position which would have allowed him to be merely an indifferent spectator of the struggle for life of his less favoured *confrères*, he nevertheless took part in every effort to improve the social condition of the profession, and till his death he was the Chairman of the Practitioners' Union of his quarter.

Professor Bardeleben was born in 1819 in Frankfort-on-the-Oder, where his father was a lawyer, and having studied in Berlin and Heidelberg he became qualified in 1842. He was elected assistant to Professor Nägeles' gynæcological clinic, and afterwards became Prosector and Teacher of Anatomy. He continued anatomical study, and from Heidelberg went to Giessen, where he began his surgical work. When still a rather young man he was elected Ordinary Professor of Surgery at the University of Greifswald, where he lived from 1848 to 1868. In 1868 he went to Berlin as successor to the late Professor Züngken. He took part in the wars of 1866 and 1870. He received the first class of the Iron Cross for his services, a distinction which was conferred on only six or seven medical men. After the war he was made Surgeon-General of the army medical staff and the high military rank of General-Major was granted him. Several times he was Dean of the Faculty and Rector of the University. He was one of the founders of the German Surgical Association, and for many years one of the presidents of the Berlin Medical Society. He attended the meetings very punctually and regularly, but seldom took part in the discussions. Especially he seemed to dislike polemical debates, and it was an interesting sight to see the dignified and venerable old man looking down with Olympian tranquillity and a sarcastic smile on some dispute for priority. The sorrow at his unexpected death is deep and general in Berlin.

DEATHS OF EMINENT FOREIGN MEDICAL MEN.—The deaths of the following eminent foreign medical men are announced:—Dr. Geo. K. Smith, formerly Assistant Professor of Surgery in Long Island College Hospital, Brooklyn.—Dr. Rand, a well-known surgeon, also of Brooklyn, New York.—Dr. A. Tebaldi, Professor of Clinical Psychiatrics in the University of Padua.—Dr. J. Vamvas, Professor of Hygiene in the University of Athens.

Medical News.

DURHAM UNIVERSITY.—At a convocation held at Durham on Saturday, Sept. 28th, the following degrees in Medicine and Surgery were conferred by the warden, Dean Kitchin:—

M.D. (ad eundem).—W. Ewart, Calus College, Cambridge.
M.D. (Practitioners).—B. Duke, E. Duke, R. Hartley, G. H. Hetherington, J. E. Richards, H. A. Smith, W. Sykes, W. F. Thomas, W. P. Turner, and J. F. Woods.
M.D.—J. H. Baker, J. Braithwaite, T. Beattie, W. A. Dow, J. W. H. Eyre, W. E. Harker, R. L. Meade King, G. Metcalfe, F. B. Rutter, F. Syrett, and L. C. Thorne Thorne.
M.B.—O. Bevan, W. Turnbull, N. C. Gwynn, J. G. Grace, L. G. Fraser, H. L. Hatch, J. R. Adamson, A. Baker, S. Barker, W. T. Carpenter, H. Crichton, R. C. de Lacey, W. G. Fell, L. Fothergill, H. H. Gourleck, G. W. Harbottle, A. H. Hobbs, J. T. Manford, C. M. O'Brien, J. H. Rowell, F. R. Sutton, C. Stewart, F. L. Walker, and W. J. Rowland.
B.S.—J. R. Adamson, A. Baker, S. Barker, O. Beven, H. Crichton, R. C. de Lacey, L. G. Fraser, W. G. Fell, N. C. Gwynn, G. W. Harbottle, H. L. Hatch, A. H. Hobbs, E. R. Kendall, J. T. Manford, C. Meaden, W. H. Rowell, F. R. Sutton, C. Stewart, W. Turnbull, F. S. Walker, and J. J. Grace.
B. Hy.—R. Green.

FOREIGN UNIVERSITY INTELLIGENCE.—*Breslau:* Dr. A. Barth of Marburg has been appointed Extraordinary Professor of Otology, Rhinology, and Laryngology.—*Budapest:* The chair of Pathological Anatomy has been divided between Drs. Pertik and Genersich. Drs. Feuer, Szili, and St. Csapodi have been promoted to Extraordinary Professorships of Ophthalmology.—*Cracow:* Drs. H. Jordan and Anton Mars have been promoted to Ordinary Professorships of Midwifery and Gynæcology.—*Göttingen:* Dr. A. Cramer has been recognised as *privat-docent* in Psychiatrics.—*Gratz:* Drs. Ebner and Bleichsteiner have been granted the honorary title of Extraordinary Professor.—*Innsbrück:* Dr. F. Dimmer of Vienna has been appointed to the chair of Ophthalmology in succession to Dr. Czermak. Dr. A. Beck of Cracow has been appointed Extraordinary Professor of Physiology.—*Marburg:* Dr. T. Axenfeld has been recognised as *privat-docent* in Ophthalmology.—*Prague* (German University): Dr. J. V. Rohon has been appointed Extraordinary Professor of Histology.—*Vienna:* Drs. A. Klein, T. Mannaberg, and F. Obermayer have been recognised as *privat-docenten* in Internal Medicine, and Dr. R. Braun von Fernwald as *privat-docent* in Midwifery and Gynæcology.—*Würzburg:* Dr. Riese has been recognised as *privat-docent* in Surgery.

FOOTBALL CASUALTY.—On Saturday last, while playing a match at Cardiff between the Cardiff and Barnstaple teams, the Cardiff International half-back sustained a fracture of his jaw.

MEDICAL MAGISTRATE.—Mr. John C. Baird, M.B., Ch.B. Melb., of Healesville, Victoria, has been made a Justice of the Peace for Victoria, Australia.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL.—The First Entrance Scholarship in Natural Science, of the value of £150, has been awarded to Mr. Frank B. Skerrett; the second, of the value of £60, being divided between Messrs. Walter B. Fry, George W. Hare, and Alfred B. Lindsey, bracketed equal. The Entrance Scholarship, value £50, for students from the Universities, has been awarded to Mr. Percy W. G. Sargent, B.A., of St. John's College, Cambridge.

WE regret to learn that Mr. A. S. Ivens, medical officer of health of Walton-on-Naze, has been seriously indisposed and compelled to leave home for the sake of rest and change. The urban district council, on Sept. 26th, elected Mr. W. E. Dawson, of Walton-on-Naze, to be acting medical officer of health during Mr. Ivens's absence. Mr. Dawson, who is a member of the district council, in acknowledging the appointment, said that he was willing to undertake the duty without emolument as an act of friendship to Mr. Ivens.

NORTH-WESTERN POOR-LAW CONFERENCE.—At the twenty-first annual meeting of the North-Western Poor-law Conference opened at Ulverston, Lancashire, on Sept. 27th, under the presidency of Sir John Hibbert, papers were read by Mr. Moore (Burnley) on Sanitation in Relation to Poor-law Administration, and by Dr. J. Milson Rhodes of Chorlton, Manchester, on Classification of Paupers by Workhouses. Dr. Rhodes said that at the passing of the Act in 1834 small administrative areas were created in order that the friends of inmates might visit the workhouses without difficulty or expense, but that by reason of the modern facilities for travelling many of the advantages of larger areas were now attainable by voluntary combinations among the existing areas. The benefits of large administrative areas were apparent to the early Poor-law reformers, and Mr. Day, an assistant commissioner, half a century ago strongly advocated the classification of paupers in a combined system of workhouses rather than in the separate wards of a single building, for in the latter case there is no guarantee for the permanence of the system, and classification soon drifts into non-classification. Enlargement of the present Poor-law areas would entail serious difficulties, and in many cases the amalgamation of two or even three unions would fail to yield satisfactory results; but voluntary combination (not amalgamation) of boards of guardians for the purpose of dealing with certain classes of paupers is an easy resource, the practicability of which has been proved by various metropolitan establishments for pauper children and for imbeciles, and by the arrangements for tramps and test cases at Liverpool and West Derby. In this way, also, satisfactory provision could be made for the sick by the employment of an adequate staff of trained nurses, whereas, under the existing system, in some of the smaller workhouses there is only one nurse, in others there is no nurse, and only last year Dr. Rhodes visited a workhouse where the method of classification was so faulty that male lunatics were placed in the male venereal wards. Recognising the advantages of large administrative areas, the Garstang, Preston, and Fylde district councils have just resolved on a scheme, not of amalgamation, but of combination, for the purpose of providing hospital accommodation for the infectious cases, especially small-pox, arising in a tract of country twenty miles square. For the accommodation of idiot children combination should be on a much larger scale, preferably by the conjoint action of Lancashire and Yorkshire. In the workhouses of the county palatine there are 2296 lunatics and probably about 600 sane epileptics, but these two classes ought to be kept apart, many of the latter being able to work, though unable to find employment on account of their infirmity. Vagrancy has not been in the least diminished by the system of two days' detention, and is not likely to be reduced except by the progress of education or by some modification of the colony system, for which some of the country workhouses, situated where land is cheap, might be made available by means of combination. After a discussion the principle advocated by Dr. Rhodes was recommended for the consideration of boards of guardians, especially with reference to imbeciles and epileptics.—On Sept. 28th Mrs. Pankhurst (Chorlton) read a paper on the Duties of Boards of Guardians in Times of Exceptional Distress. Sir Walter Foster, M.P., and the President joined in the subsequent discussion and the proceedings terminated.

UNIVERSITY COLLEGE, LONDON: SESSION 1895-96.—Medical Entrance Exhibitions; 131 guineas, Thomas C. Savage; 55 guineas, H. W. Reynolds; 55 guineas, William Reith Scroggie.

LITERARY INTELLIGENCE.—The Roxburghe Press is about to issue the *Nursing World and Hospital Record*, a journal for trained nurses, who, it is calculated, number nearly 30,000 in this country alone. The *Nursing World* is a development and entire re-organisation of the journal known for the last five years as the *Popular Medical Monthly*, and will be conducted in a broad spirit and without being the organ of a section or clique. It will contain many new and interesting features and a number of articles from the pens of well-known and competent writers. Its price will be one penny.

VOLUNTEER AMBULANCE SCHOOL OF INSTRUCTION.—The winter work of this school commenced on Monday last at the headquarters of the London Rifle Brigade, Bunhill-row, E.C., when two large companies paraded for instruction under Surgeon-Major H. F. Stokes, senior medical officer instructor. The present classes will conclude with the official inspection on Dec. 9th. It is notified for general information that no more men can be taken in either class after Oct. 7th. Among the officers who have recently joined for a course of instruction are Surgeon-Major T. F. Fleetwood, F.R.C.S., Victorian Military Forces, South Australia, and Surgeon-Captain J. H. Cox, Cape Town Volunteer Medical Staff Corps.

WE are sorry to announce that Mr. Trimmer, the Secretary of the Royal College of Surgeons, was knocked down and hurt as he was leaving the College on Wednesday evening. A thief made a snatch at his chain and succeeded in getting off with it and with a bunch of seals which were attached. Mr. Trimmer endeavoured to follow the thief, but was at once thrown on his head by a confederate. His face was badly cut, but he managed to reach the College; he was at once taken to King's College Hospital, where his injuries were carefully attended to. Mr. Trimmer was able to return to his home later in the evening, and on inquiry at the College we are pleased to hear that he is not seriously injured.

GUY'S HOSPITAL ENTRANCE SCHOLARSHIPS.—An Entrance Scholarship in Arts of the value of £100 was awarded to Mr. G. Lewin, who was educated at the City of London School; and the Second Entrance Scholarship in Arts of the value of £50 was awarded to Mr. F. G. Gibson, who was educated at Canterbury College, New Zealand. Certificates of Honour were obtained by the following:—Mr. M. Feldman, Jews' College; Mr. F. S. S. George, Dulwich College; Mr. H. F. Hatfield, Dulwich College; Mr. H. D. Kempthorne, St. John's Foundation School, Leatherhead. The Entrance Scholarship in Arts of the value of £30 for dental students was awarded to Mr. H. A. G. Butler, Douglas School, Cheltenham. The Entrance Scholarship in Science of the value of £150 was awarded to Mr. P. W. L. Camps, and the Second Entrance Scholarship in Science of the value of £60 was awarded to Mr. S. Hodgson. Certificates were awarded to Mr. E. A. Miller and Mr. D. Forsyth.

DIPHTHERIA IN LONDON.—The satisfaction which was felt at the diminished number of deaths from diphtheria in London in the third week of September has been more than counterbalanced by the excessive number chronicled last week. The totals of registered deaths in the first three weeks of last month were 38, 55, and 37 respectively, the latter being even below the corrected decennial average for the particular week; but last week they rose to 56, being 12 in excess of the average, and the highest figure since the week ended Aug. 3rd, when the deaths were one more. Of the 56 deaths, 7 are credited to Camberwell, 5 each to St. Pancras, Islington, Bethnal-green, and Lambeth sanitary area. They all occurred in persons under twenty years of age, 37 being in children under five years of age. But high as were the deaths from this disease in London proper, there were in addition 17 deaths registered in the outer ring of the metropolis, as many as 11 of these being located in the West Ham, and other 4 in the Edmonton registration districts. The attacks in London were also very numerous last week, and the admissions to hospital identical with those of the preceding week—namely, 114. The cases remaining under treatment in hospitals on Saturday last numbered 673, a total which has not been equalled since Aug. 10th, when it stood at 689. The problem of diphtheria in our towns is evidently becoming more complex.

PRESENTATION TO SIR PETER EADE, M.D. Lond.—On Sept. 25th the corporation of Norwich presented the Mayor, Sir Peter Eade, with the honorary freedom of the city in recognition of the eminent services which he has rendered to Norwich. The Deputy Mayor, who presided, said that the Mayor was now holding office for the third time, the previous occasions having been in 1883–84 and 1893–94, and that he has zealously maintained the dignity of his civic position, a task in which he has been ably supported by Lady Eade. In admitting him to the freedom of the city his fellow citizens have bestowed on him the highest honour at their disposal, and a distinction reserved for exceptional cases. A handsome and elaborate silver casket containing a richly illuminated scroll was then handed to the Mayor, who signed the roll and made the customary declaration. Sir Peter Eade, after warmly thanking the corporation for the honour which they had done him, said that he was not one of those who thought that a professional man should keep aloof from any duties lying outside his special province. On the contrary, he considered that it was beneficial, even from a professional point of view, to engage in pursuits which ensured a diversity of mental occupation. He reminded the company that in Norwich very few medical men had been mayors, though some had been sheriffs. In the last hundred years, excluding himself, there had been only three medical mayors—namely, Dr. Rigby, Mr. J. Goodwin Johnson, and Mr. Nichols. In the evening another ceremony took place in the picture gallery of the Castle Museum, where Lord Walsingham, in the presence of a large and distinguished company, presented Sir Peter Eade with his portrait.

BOOKS ETC. RECEIVED.

ALLENSON, H. R., Paternoster-row, London.
Fred. C. Roberts of Tientsin; for Christ and China. By Mrs. Bryson. With an introduction by the Rev. F. B. Meyer, B.A. 1895. pp. 222. Price 3s. 6d.

Baccelli in Rom; autorisirte deutsche Ausgabe (Williams and Norgate, Henrietta-street, Covent-garden, London).—Illustrated Modern Art and Literature; vol. i., No. 10 (Modern Art Publishing Company, 68, Fleet-street, London, E.C.); price 1s.—Notes from Spa Practice; by Samuel Hyde, M.D. (reprint from Medical Magazine, vol. iv., March-April, 1895).—The British Gynæcological Journal; edited by L. Napier, M.D., F.R.S. Edin.; Parts 40, 41, and 42 (J. Bale and Sons, Great Titchfield-street, London, W.) price 3s. 6d. each.—Monatshefte für Praktische Dermatologie, unter Mitwirkung von P. Taenzer in Bremen, von P. G. Unna; Zwanzigster Band; 1895; Januar bis Juni; mit Sieben Tafeln (Leopold Voss, Hamburg und Leipzig, 1895).—Magazines, &c., for October: The Strand Magazine, The Picture Magazine, Illustrated English Magazine, Boy's Own Paper, Girl's Own Paper, Leisure Hour, Sunday at Home, Pall Mall Magazine, Westminster Review, Contemporary Review, Chapman's Magazine.

Appointments.

Successful applicants for Vacancies, Secretaries of Public Institutions, and others possessing information suitable for this column, are invited to forward it to THE LANCET *Office, directed to the Sub-Editor, not later than 9 o'clock on the Thursday morning of each week for publication in the next number.*

AITKEN, C. CRAWFORD, M.B., C.M. Edin., has been appointed Junior House Surgeon to the Cumberland Infirmary.

ASPINALL, J., M.R.C.S., has been appointed Medical Officer of Health for the Smallthorne Urban Sanitary District, vice Walker.

BEALE, P. T. B., F.R.C.S. Eng., has been appointed Demonstrator of Histology and reappointed Lecturer on Elementary Biology in King's College, London.

BRODRICK, C. C., L.R.C.P., L.R.C.S. Edin., has been appointed Medical Officer of Health for the Tavistock Rural Sanitary District.

BIERNACKI, JOHN, M.B., C.M. Glasg., L.R.C.P. Edin., &c., has been appointed Medical Superintendent of the West Ham Fever Hospital.

COLEY, J. G. E., M.B., B.Ch. Oxon., L.R.C.P. Lond., F.R.C.S., D.P.H. Camb., has been appointed Medical Officer of Health for the Malton and Morton Rural Sanitary Districts.

COLLINS, A. B., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Yapton District of the Westhampnett Union.

DOCKRAY, JOHN S., B.Sc. Lond., M.R.C.S., L.R.C.P., has been appointed House Surgeon to the Manchester Southern and Maternity Hospitals.

DOW, JAS. W., M.D., Ch.M. Toronto, has been appointed Health Officer for the Shire of Rosedale, Victoria, Australia.

EASBY, W., M.D., has been appointed Medical Officer of Health for the Peterborough Rural District Council, vice W. E. Paley, deceased.

FLETCHER, JAMES, M.B., C.M. Aberd., has been appointed Resident Physician to the Aberdeen City Hospital.

FLINT, T. B., L.R.C.P. Lond., M.R.C.S. Eng., has been appointed House Surgeon to the Clinical Hospital, Manchester.

GIDLEY, G. G., L.R.C.P. Lond., M.R.C.S., has been appointed District Medical Officer for the Tiverton Union.

HOGGAN, BERTRAM B., L.R.C.P., L.R.C.S. Edin., L.F.P.S. Glasg., has been appointed Public Vaccinator at Romsey, Victoria, Australia.

HOLTON, F. W. P., M.R.C.S., has been appointed Medical Officer for the Tenth Sanitary District of the West Ham Union.

HOPE, GEO. J. B., M.A., M.B., C.M., has been appointed Medical Officer of Health to Scarborough Rural District Council, vice Cuff, resigned.

JOHNSTON, J. W., M.D., M.S. Edin., has been appointed Medical Officer for the Workhouse and the First Sanitary District of the Fordingbridge Union.

KENDALL, B. C., L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the Wendron Sanitary District of the Helston Union, vice Seville, resigned.

LAWSON, T. C., M.R.C.S., has been appointed Medical Officer for the Stogursey Sanitary District of the Williton Union.

MCCORMACK, CHARLES VINCENT, L.R.C.P. Lond., M.R.C.S. Lond., has been appointed Superintendent of the Corporation Hospital, Bootle, Lancashire.

MACDONALD, D. S., M.B., Ch.M. Edin., has been appointed City Health Officer for Rockhampton, Queensland.

MCBREARTY, JAS., L.F.P.S. Glasg., has been appointed Surgeon-Captain to the Greymouth Naval Artillery Volunteers, New Zealand.

MCCAW, HUGH, M.B., Ch.M. Glasg., has been appointed Public Vaccinator for the District of East Taieri, New Zealand.

MAIN, HARRY F., M.B., Ch.B. Melb., has been appointed Medical Officer for the Kyneton Hospital, Victoria, Australia.

PEEBLES, F. M., M.B. Melb., has been appointed Honorary Medical Officer to the Bendigo Hospital, Victoria, Australia, vice MacGillivray.

ROMER, FRANK, L.R.C.P. Lond., M.R.C.S., has been appointed Medical Officer for the No. 3 Sanitary District of the Malmesbury Union, vice A. E. Clarke, resigned.

ROSS, JOHN, M.B., Ch.M. Edin., has been appointed a Public Vaccinator for the District of Waipawa, New Zealand.

RICHARDS, WM. H., L.S.A., has been appointed District Medical Officer for the Cardiff Union.

SEYLER, C. A., has been appointed Analyst for the County of Glamorgan, vice Morgan.

SHOWMAN, LOUIS F., L.R.C.P., L.R.C.S., L.M. Edin., L.F.P.S. Glasg., has been appointed Health Officer for the Wirrimbirchip Shire, Victoria, Australia.

SKINNER, E. W., M.D., C.M. Edin., has been reappointed Medical Officer of Health to the Rye Rural District Council.

STEVENS, F. J., M.R.C.S., D.P.H., R.C.P.S. Eng., has been appointed Medical Officer of Health for the Parish of Camberwell.

Digitized by Google

TOOTH, H. H., M.D. Cantab., F.R.C.P., M. Lond., M.R.C.S., has been appointed Assistant Physician to St. Bartholomew's Hospital.
WOOLLEY, GEO. T., M.R.C.S. Eng., has been appointed Consulting Surgeon to the Maldon Hospital, Victoria, Australia.
YELF, R. R. B., M.B., C.M. Edin., has been appointed Medical Officer for the Moreton Sanitary District of the Shipston-on-Stour Union.

Vacancies.

For further information regarding each vacancy reference should be made to the advertisement (see Index).

CHESTERFIELD AND NORTH DERBYSHIRE HOSPITAL AND DISPENSARY, Chesterfield.—Junior House Surgeon and Dispenser for three years. Salary £50 per annum, with board, apartments, and laundress.
EAST LONDON HOSPITAL FOR CHILDREN AND DISPENSARY FOR WOMEN, Glamis-road, Shadwell, E.—Assistant Physician, to see out-patients.
EAST SUSSEX COUNTY COUNCIL.—Consulting Medical Officer for one year. Honorarium of 100 guineas and travelling expenses.
HOSPITAL FOR CONSUMPTION AND DISEASES OF THE CHEST, Brompton.—Resident House Physicians.
HOSPITAL FOR WOMEN (the Loudon School of Gynæcology), Soho-square, W.—Clinical Assistants.
LONDON HOSPITAL, Whitechapel, E.—Medical Electrician.
MANCHESTER HOSPITAL FOR CONSUMPTION AND DISEASES OF THE THROAT AND CHEST.—Resident Medical Officer at Bowden, Cheshire. Salary £60 per annum, with board, apartments, and washing.
METROPOLITAN HOSPITAL, Kingsland-road, N.E.—Assistant Surgeon.
MILLER HOSPITAL AND ROYAL KENT DISPENSARY, Greenwich-road, S.E.—Junior Resident Medical Officer, for six months. Salary at the rate of £30 per annum, with board, attendance, and washing.
NORFOLK COUNTY ASYLUM, Thorpe, Norwich.—Junior Assistant Medical Officer, unmarried. Salary £110 per annum, with £10 annual increase to £160, with board (no liquors), lodging, and washing.
ROYAL HOSPITAL FOR DISEASES OF THE CHEST, City-road, London, E.C.—Resident Medical Officer for six months. Salary at the rate of £100 per annum, with furnished apartments and board.
SHEFFIELD ROYAL HOSPITAL.—House Physician, for one year, unmarried. Board (exclusive of wine and beer) and lodging, an an honorarium of 25 guineas. Also Junior Assistant House Surgeon, unmarried. Salary 60 guineas per annum, with board (exclusive of wine and beer) and lodging.
SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—House Surgeon. Salary £100, with board and residence.
SOUTH DEVON AND EAST CORNWALL HOSPITAL, Plymouth.—Assistant House Surgeon for six months. Board and residence provided, and an honorarium of £10.
SUSSEX COUNTY HOSPITAL, Brighton.—Fourth Resident Medical Officer. Unmarried. Salary £30 per annum, with board, washing, and residence in the hospital.
SWANSEA HOSPITAL.—House Physician, for one year. Salary £60 per annum, with board, lodging, and laundress.
THE RURAL DISTRICTS OF BUNTINGFORD, HADHAM, HERTFORD, STANSTED, AND WARE, AND THE URBAN DISTRICTS OF BISHOPS STORTFORD, HERTFORD, HODDESDEN, AND WARE.—Medical Officer of Health for the above districts. Salary £600 per annum, including travelling and all other expenses. Applications to the Clerk of the Joint Committee, Council Offices, Baldock-street, Ware, Herts.
WIRRAL CHILDREN'S HOSPITAL, Woodchurch-road, Birkenhead.—Resident House Surgeon. Salary £50 per annum, with board, lodging on the premises, and washing.

Births, Marriages and Deaths.

BIRTHS.

SMELT.—On Sept. 29th, at 371, Holloway-road, N., the wife of C. A. Casterton Smelt, M.B., C.M., of a son.
THOMSON.—On Sept. 25th, at 243, Queen's-road, New Cross-gate, S.E., the wife of David Thomson, L.R.C.P. Edin., L.R.C.S. Edin., L.F.P.S. Glas., of a daughter.
WHITAKER.—On Sept. 28th, at Cove House, Sandycove, county Dublin, the wife of J. Minchin Whitaker, L.R.C.S. & P. Edin., of a son.

MARRIAGES.

ASHWELL—LYON.—On Sept. 25th, at Pontefract Parish Church, Herbert George Ashwell, M.R.C.S., &c., of Nottingham, to Elizabeth Beatrice Lyon, eldest daughter of Mr. J. G. Lyon, J.P., of Carleton Close, Pontefract.
BALLANCE—MAUNSELL.—On Sept. 25th, at All Saints', Raheny, county Dublin, H. Stanley Ballance, M.D., B.S. Lond., of 4, Royal-terrace, Weston-super-Mare, to Kathleen Isabella, daughter of John Maunsell, Esq., Edenmore, Raheny.

DEATHS.

BELLOT.—On Sept. 24th, at his residence, Moreton Lodge, Leamington, William Henry Bellot, M.D. Erlangen, F.R.C.S. Eng., aged 84.
DAVISON.—On Sept. 12th, at Holloway-road, James Campbell Davison, M.D. Brux., F.R.C.S., L.R.C.P. Edin., Belgian Distinguished Service Order, aged 55.
HEATON.—On Sept. 30th, at Hastings, Alan Baldwin Heaton, M.B., of St. James's-street, S.W., in his 27th year.
MASSY.—On Sept. 27th, at Northwood Lodge, Bournemouth, Surgeon-General Hampden Hugh Massy, C.B., aged 75.

N.B.—A fee of 5s. is charged for the insertion of Notices of Births, Marriages and Deaths.

OPERATIONS.

METROPOLITAN HOSPITALS.

MONDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), St. George's (1 P.M.), St. Mark's (2 P.M.), Chelsea (2 P.M.), Samaritan (Gynæcological, by Physicians, 2 P.M.), Soho-square (2 P.M.), Royal Orthopædic (2 P.M.), City Orthopædic (4 P.M.), Gt. Northern Central (Gynæcological, 2.30 P.M.).
TUESDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), Guy's (1.30 P.M.), St. Thomas's (3.30 P.M.), Westminster (2 P.M.), West London (2.30 P.M.), University College (2 P.M.), St. George's (1 P.M.), St. Mary's (1.30 P.M.), St. Mark's (2.30 P.M.), Cancer (2 P.M.).
WEDNESDAY.—St. Bartholomew's (1.30 P.M.), University College (2 P.M.), Royal Free (2 P.M.), Middlesex (1.30 P.M.), Charing-cross (3 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), King's College (2 P.M.), National Orthopædic (10 A.M.), St. Peter's (2 P.M.), Samaritan (2.30 P.M.), Gt. Ormond-street (9.30 A.M.), Gt. Northern Central (2.30 P.M.).
THURSDAY.—St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), University College (2 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), London (2 P.M.), King's College (2 P.M.), Middlesex (2 P.M.), Soho-square (2 P.M.), North-West London (2 P.M.).
FRIDAY.—London (2 P.M.), St. Bartholomew's (1.30 P.M.), St. Thomas's (3.30 P.M.), Guy's (1.30 P.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), King's College (2 P.M.), Cancer (2 P.M.), Chelsea (2 P.M.), Gt. Northern Central (2.30 P.M.).
SATURDAY.—Royal Free (9 A.M. and 2 P.M.), Middlesex (1.30 P.M.), St. Thomas's (2 P.M.), London (2 P.M.), University College (9.15 A.M.), Charing-cross (3 P.M.), St. George's (1 P.M.), Cancer (2 P.M.).
At the Royal Eye Hospital (2 P.M.), the Royal London Ophthalmic (10 A.M.), the Royal Westminster Ophthalmic (1.30 P.M.), and the Central London Ophthalmic Hospitals operations are performed daily.

SOCIETIES.

WEDNESDAY.—LARYNGOLOGICAL SOCIETY OF LONDON (20, Hanover-sq., W.).—5 P.M. Cases will be shewn by Dr. Leonard Roper and Mr. Charters J. Symonds. Pathological Specimens by Dr. Felix Semon and Dr. Scanes Spicer.
SOUTH-WEST LONDON MEDICAL SOCIETY (Workhouse Infirmary, St. John's Hill, New Wandsworth).—8 P.M. Dr. J. B. Neal will show several cases of interest from the Infirmary.
HUNTERIAN SOCIETY.—8.30 P.M. Address by the President (Mr. Charters J. Symonds). Mr. F. Rowland Humphreys: The Infectious Nature of Rheumatism.
THURSDAY.—BRITISH GYNÆCOLOGICAL SOCIETY.—Specimens by Dr. R. H. Hodgson (Multilocular Ovarian Tumour undergoing Fatty Degeneration) and Dr. Collins of Cardiff. Paper by Mr. Bowreman Jessett: A New Method of performing Abdominal Hysterectomy, with five successful cases.
FRIDAY.—CLINICAL SOCIETY OF LONDON.—8.30 P.M. Introductory Address by the President. Papers:—Mr. Arbuthnot Lane: Three cases of Excision of the Temporo-maxillary Articulation in Children.—Sir Dyce Duckworth: Case of Sudden Death due to Cardiac Syphiloma.—Mr. Barker: Traumatic Derangement of the Knee-joint due apparently to Fracture of the Spine of the Tibia; Exploratory Arthrotomy.—Dr. Radcliffe Crocker: Impetigo Contagiosa Gyrata.

LECTURES, ADDRESSES, DEMONSTRATIONS, &c.

MONDAY.—LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 1 P.M., Mr. W. Lang: Clinical Examination of the Eye.—London Throat Hospital, Great Portland-street, W., 8 P.M., Mr. W. R. H. Stewart: Examination of the Ear.
TUESDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 2 P.M., Dr. Percy Smith: Acute Mania.
WEDNESDAY.—NATIONAL HOSPITAL FOR THE PARALYSED AND EPILEPTIC (Bloomsbury).—3 P.M. Lecture by Dr. Beevor.
ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-square, W.C.).—5 P.M. Dr. Morgan Dockrell: Eczema.
LONDON POST-GRADUATE COURSE.—Royal London Ophthalmic Hospital, Moorfields, 8 P.M., Mr. A. Q. Silcock: Choroidal Affections, with Illustrative Cases.
WEST LONDON POST-GRADUATE COURSE (West London Hospital, W.).—5 P.M. Mr. S. Paget: Surgical Cases.
THURSDAY.—LONDON POST-GRADUATE COURSE.—Hospital for Sick Children, Gt. Ormond-st., 3.30 P.M., The Medical Registrar: Pathological Demonstration.—National Hospital for the Paralysed, Bloomsbury, 2 P.M., Dr. Gowers: Clinical Lecture.—Central London Sick Asylum, Cleveland-st., W., 5.30 P.M., Mr. John Hopkins: Cases in the Wards.
FRIDAY.—LONDON POST-GRADUATE COURSE.—Bacteriological Laboratory, King's College, 3 to 5 P.M., Prof. Crookshank: The Microscope and Methods of Cultivation.
SATURDAY.—LONDON POST-GRADUATE COURSE.—Bethlem Hospital, 11 A.M., Dr. Hyslop: Hysterical and Delirious Mania.
ST. JOHN'S HOSPITAL FOR DISEASES OF THE SKIN (Leicester-sq., W.C.).—5 P.M. Dr. Morgan Dockrell: Psoriasis and Seborrhœic Dermatitis.

Notes, Short Comments, and Answers to Correspondents.

EDITORIAL NOTICE.

IT is most important that communications relating to the Editorial business of THE LANCET should be addressed *exclusively* "TO THE EDITORS," and not in any case to any gentleman who may be supposed to be connected with the Editorial staff. It is urgently necessary that attention be given to this notice.

It is especially requested that early intelligence of local events having a medical interest, or which it is desirable to bring under the notice of the profession, may be sent direct to this Office.

Lectures, original articles, and reports should be written on one side only of the paper.

Letters, whether intended for insertion or for private information, must be authenticated by the names and addresses of their writers, not necessarily for publication.

We cannot prescribe or recommend practitioners.

Local papers containing reports or news paragraphs should be marked and addressed "To the Sub-Editor."

Letters relating to the publication, sale, and advertising departments of THE LANCET *should be addressed "To the Manager."*

We cannot undertake to return MSS. not used.

MANAGER'S NOTICE.

"THE LANCET" AND ACCIDENT INSURANCE.

A LITHOGRAPHED CIRCULAR LETTER, emanating from an office in the Strand district, is being sent to members of the medical profession, offering to supply them with THE LANCET, in conjunction with an accident insurance policy. The Proprietors of THE LANCET are in no way connected with the scheme (of which they cannot approve), and were not aware of its inception until their attention was called to it by a reader who had received the circular.

MEDICAL MEN AND INTEREST IN COMPANIES FOR THE SALE OF MEDICAL FOOD.

MR. WM. COLEMAN persists in sending round the profession from time to time offers of debentures in his company, which is constituted for the sale of a compound of extract of meat and malt wine. Our object now is not so much to discuss the merits of this preparation, but to dissuade all medical men from becoming shareholders in a company for its sale. Such a position is inconsistent with their duty and their dignity as medical men.

MESSRS. MABIE, TODD, AND BAIRD of Cheapside have sent us one of their Swan Fountain Pens—in case, probably, we had never heard of them. But we have, and use them constantly, and would not be without them. They are a revelation to anyone who has hitherto had to put up with a steel pen.

Nemo.—We believe that almost any London hospital will receive a probationer under the circumstances mentioned.

THE PERCUTEUR IN APHONIA.

To the Editors of THE LANCET.

SIRS,—The occasional instantaneous action of the percuteur was well illustrated in a recent case. On Sept. 22nd a woman aged twenty-three years was brought by a friend to ask for a ticket to attend the throat hospital, as she had for three weeks been unable to speak above a whisper. The percuteur was applied for one minute over the thyroid cartilages, and at once she could speak in a loud voice, much to her own and her companion's astonishment. The improved condition has continued up to the present date.

I am, Sirs, yours faithfully,

Oct. 1st, 1895. RICHARD NEALE, M.D. Lond.

Mr. W. Garland Soper desires to know any references to any opinions, fact, or figures with respect to the desirability or otherwise of muzzling dogs. Our correspondent's attention may be directed to an annotation in our present issue.

B.—Our correspondent had better apply direct at the offices of any of the great liners—P. & O., Orient, Cunard, &c. Most of them, we believe, require candidates to serve for at least a year.

AN UNQUALIFIED PRACTITIONER AT PENARTH.

UNQUALIFIED practice is the concern of the public. Life is sacrificed to it, and coroners' inquests have to be held. A case in point has just occurred at Penarth. A child four weeks old was ill with convulsions, and the parents called in a person described in the report of the inquest as "Doctor Graves." This gentleman has no qualification. So complete is the impression he produces of being a proper medical man that one of the jurors said that he had lived in Penarth all his life and never knew till then that Graves was not a qualified medical man. The people who sent for him on this occasion thought so too. Yet the jury added to their verdict of "Death from natural causes" "that the nurse was to blame for not calling in a properly qualified man." This seems scarcely fair till the law is so amended that such deception as is practised on a community shall be much more severely punished than it is. If we are not misinformed, this individual has been already successfully prosecuted three times, twice under the Apothecaries' Act and once under the Medical Act.

House Surgeon.—The police are not bound to take cognisance of the facts reported to them, and consequently not bound to watch an alleged suicidal patient whilst in the hospital. At the same time we hold that they would act more in the interests of justice if they did so. Quite recently a case occurred in a London hospital in which, although it was clearly established that the patient had attempted to take his own life, the local police decided not to charge him, on condition that his friends undertook to take care of him. In this we maintain they were in the wrong. The surgeon in charge of the case advised that the Chief Commissioner of Police should be informed of the fact, thus freeing the hospital from any further responsibility.

Gadus (?).—Supposing the relations between A. and C. to be of the normal friendly character which obtains between medical neighbours, the work done by C. should be considered as done by A. and for A., leaving to A. the fees for it and the collection of them.

M.B., C.M.—None but *legally* qualified medical practitioners can give certificates of the cause of death.

AN ALLEGED FLAGRANT BREACH OF ETIQUETTE.

To the Editors of THE LANCET.

SIRS,—I shall be glad of your opinion upon the conduct of a practitioner under the following circumstances. I saw a patient, employed in the Post Office, suffering from rheumatic fever and gave him a certificate to that effect. Some days afterwards a medical man employed by the Post Office was sent down to see the case. Without calling upon me at all he visited my patient and told him he was suffering from *rheumatism*, but not *rheumatic fever*. Will you kindly say: 1. Whether it is correct for a medical man to call upon another's patient without consulting him? 2. Whether it is correct for a medical man in any case, and especially under the above circumstances, to contradict another's diagnosis to the patient in the absence of the other practitioner, even though he deem the diagnosis a mistake? 3. What can be the difference between acute rheumatism and rheumatic fever (there is no doubt whatever about the acuteness of the disease—temperature 104°, &c.)? 4. After the lapse of a week, is the diagnosis of a casual visitor more likely to be correct than that of the regular medical attendant, who has seen the case from the commencement?

I am, Sirs, yours faithfully,

Sept. 24th, 1895. W. J. R.

*** 1. It is not right or usual for a medical man, whatever his official position, to visit another's patient without consulting him.—2. It is especially wrong to contradict the diagnosis of another practitioner in his absence and without giving him the chance of justifying it.—3. Acute rheumatism and rheumatic fever are synonymous terms, and rheumatism with a temperature of 104° F. is properly certified as rheumatic fever. We would venture to suggest that our correspondent may have been misinformed to some extent. He should see the medical officer of the Post Office, of whom he seems to have just right to complain.—ED. L.

H. B.—It is not necessary in all cases to have a post-mortem examination. If the medical man does not feel justified in giving an opinion as to the cause of death, of course he is not bound to do so. The entire responsibility rests with the coroner.

Dr. Edwin A. Starling is thanked for his courteous letter. We fear, however, that we shall not be able to carry out his suggestion.

HOMES FOR CHRONIC MELANCHOLIACS.

To the Editors of THE LANCET.

SIRS,—I should be exceedingly obliged if any reader of THE LANCET could tell me of an institution where a lady suffering from chronic melancholia could be admitted on the payment of not more than £40 per annum.

I am, Sirs, yours faithfully,

Sept. 28th, 1895. G. P.

"PRACTICE IN SOUTH AFRICA."

To the Editors of THE LANCET.

SIRS,—Recent residence and practice in South Africa qualifies me to answer "Scot's" queries contained in THE LANCET of Sept. 21st. South African medical practice may be divided into three classes: (1) in towns; (2) in country villages; and (3) in native districts.

In towns.—I can confidently say that every town is adequately supplied with able medical men, and that in Cape Town and Johannesburg at least the supply largely exceeds the demand. Vacancies arising are filled up by practitioners from the country, as a rule. Fees are certainly higher than at home, but living is proportionately dearer. I would strongly dissuade any stranger from attempting to start practice in a South African town unless prepared to struggle and wait as he would at home.

In country villages.—The bulk of the profession is engaged in this kind of practice, which still is very profitable in certain parts. The villages vary from merely half-a-dozen tin shanties (forming a centre for a scattered farming population) to places of 3000 to 5000 inhabitants. Living is decidedly poor, and the accommodation, society, and practice in places are decidedly rough. In Cape Colony there are few places unsupplied with medical men; but in the Orange Free State and Transvaal there are still hamlets and districts where practice and a handsome income are to be had by simply setting up. South African country people, particularly the Boers, welcome a new medical man in a way that astonishes one accustomed to the difficulties of European practice. The old-established "district surgeon" frequently sees a goodly slice of his practice taken off by the arrival of a young practitioner, "fresh from Europe with all the latest treatments," and a such-like flourish of trumpets. Fees are high in these places, especially for medicine, and country journeys are paid for at the rate of £1 an hour. Living, on the whole, costs about the same as at home; but luxuries are very dear, and much that is regarded as a necessity at home becomes a luxury in South Africa. It must be remembered that the Boers are accustomed to receiving quite twelve months' credit from their medical men; but they are good, although slow, payers. I can again confidently state that a steady practitioner, who does not mind a roughish and isolated life, will easily find a living, and in certain districts a really handsome income, from one of these rural practices. It must be remembered also that the unwritten Cape language—a mere *patois*—must be mastered during the first few months, and, further, that South Africa sends home a yearly increasing number of able students, who, when qualified, have naturally better chances in the country than a foreigner—English, Scotch, or other.

In native districts.—These are carried on under Government appointments, and are, I believe, not profitable or enjoyable, except for those desiring sport, to study the natives, or botany, zoology, &c. There is not such keen competition for these appointments as for those in more civilised districts. The future of Mashonaland and Matabeleland is still so doubtful (despite the accounts of Stock Exchange speculators), and the cost of getting there so great, that it would be unwise of any man to go there, unless to one of the district surgeoncies—obtained, like everything else in South Africa, through influence.

Cape Colony demands a fee of £5 for registration, and an annual £5 licence to dispense; the Orange Free State requires £20 a year for licence to practise, and the Transvaal more, I believe. It is cheaper and better to take out a good supply of drugs with one, and subsequently to import direct. Indiarubber goods do not last long on the inland plains up country. It is necessary to be provided with a few letters of introduction and enough capital to live and travel until an opening is found and the practice becomes productive. For many reasons it is very indiscreet to purchase a South African practice either through a London agent or in the country; as a rule, it is money thrown away. There is a South African medical journal published monthly in Cape Town. The *Cape Argus* weekly edition (London Office: 164, Fenchurch-street) often contains advertisements of openings and practices or medical men wanted. The profession is well protected against quackery, &c., in the Colony and Free State, but not in the Transvaal; and I may say, in conclusion, that the same qualifications lead to success in a colony as in the old country, only perhaps a little colonial "bounce" is required in addition, and is acquired as quickly as the language.

I am, Sirs, your obedient servant,

Sept. 28th, 1895. M.D.

APPOINTMENT OF HOUSE SURGEON TO THE NORTH CAMBS. HOSPITAL, WISBEACH.

To the Editors of THE LANCET.

SIRS,—We were informed by letter that we were *the three* selected candidates for the above appointment out of eighteen applicants, and invited to attend the committee meeting on Oct. 1st. We naturally thought one of us would be elected. But no; for, curiously enough, after being detained about an hour and a half we were informed that a gentleman whom to our knowledge we never saw was elected. We were consoled for our disappointment by being informed by an elderly gentleman that we were too young for the post. Our ages, respectively, were thirty-nine, thirty-five, and thirty-one years. We should like to know at what age a man—having held hospital posts, as we all had—becomes capable of carrying out the duties of house surgeon to an institution containing twenty-four beds. It seems to us very unfair to make a selection of the candidates and then to appoint a gentleman who to our knowledge was not selected at all.—We enclose our cards and beg to remain,

Yours truly,

Oct. 2nd, 1895. J. S. B., D. S., AND E. B.

"THE CORPORATION DOCTOR."

To the Editors of THE LANCET.

SIRS,—Surely it is time that the voice of the General Medical Council was heard, and an authoritative judgment delivered in the case of the "corporation doctor." His action either is or is not distinctly unprofessional. If it is the former, then it ought not to be left to isolated practitioners to show resentment at his proceedings by refusing to meet him in consultation. If the latter, then the members of the profession who refuse to meet him simply because he is a "corporation doctor" ought to be made to understand that the position they take up is wrong. I understand that, in addition to being tabooed by the established practitioners in the district in which he settles, he is also debarred from the British Medical Association. If this is the case, surely the General Medical Council ought to nip the mischief in the bud, on whichever side it is springing up, and its action should be such as to leave no possible doubt of the light in which it means to regard the "corporation doctor" and the manner in which it means to treat him. Isolated members of the profession can do nothing. It requires a central authority to take the matter up and deal with it both quickly and strictly, or else the country practitioners will be compelled either to go to the wall or join the ranks of the "corporation doctor."

I beg to remain, Sirs, yours faithfully,

Sept. 29th, 1895. INDIGNANT.

"WANTED, SUGGESTIONS FOR TREATMENT."

To the Editors of THE LANCET.

SIRS,—In THE LANCET of Aug. 17th suggestions are asked for by "M.D." as to how to deal with a case of obstinate constipation. A measure which I have never known to fail to give relief, if persevered with sufficiently long and carried out properly, is deep kneading of the abdomen, together with movements calculated to strengthen and to give tone to the abdominal muscles. This should be carried out at least once daily, and on an empty stomach.

I am, Sirs, yours truly,

Eastbourne, Sept. 28th, 1895. O. H.

A QUERY.

To the Editors of THE LANCET.

SIRS,—I shall esteem it a great favour if you will kindly insert the following query in THE LANCET. The point in question is one of considerable interest to me. Is there any truth in the common belief that drowned bodies of men float face downwards, while those of women float face upwards? If so, what is the explanation? I can find no mention of the matter in any of the books to which I am able to refer, but am assured by numerous seafaring friends, from experience in the Hooghly and elsewhere, that the facts are as stated.

I am, Sirs, yours faithfully,

Sept. 30th, 1895. TEIGNMOUTH.

Mr. Sinclair Thompson (Bideford).—We certainly should not advise any English masseuse to start work in Constantinople, unless she were previously assured of the support of the English medical men. It must be remembered that massage is extensively practised in the East by Orientals of both sexes, and, in addition, there are in Constantinople some European masseuses. Native patients in the harems could, of course, be obtained all the year round, but European visitors can only be counted on during the spring months. For further information our correspondent should apply to the Physician to the English Embassy at Constantinople.

Mr. William Duncan.—Such advertisements are unseemly and unusual. We cannot give an opinion on their legality. Our correspondent tells us nothing of the circumstances.

COMMUNICATIONS not noticed in our present issue will receive attention in our next.

During the week marked copies of the following newspapers have been received:—*Blackburn Standard, Dundee Advertiser, Midland Free Press, Manchester Guardian, Hackney Mercury, North Middlesex Chronicle, Liverpool Courier, Montreal Herald, Birmingham Post, Cheshire Observer, Newcastle Leader, Bridge of Allan Reporter, Falkirk Herald, Leicester Advertiser, Loughborough Monitor, Carnarvon Herald, Sheffield Independent, Northern Whig, Belfast News Letter, The Sun, Builder, Times of India, Manchester Courier, Glasgow Evening News, Birmingham Argus, Redditch Indicator, Evening Telegraph (Dundee), Freeman's Journal, Pioneer Mail, Architect, Scotsman, Citizen, Brighton Gazette, Leeds Mercury, Bristol Mercury, Sanitary Record, City Press, Liverpool Daily Post, Newry Telegraph, Yorkshire Post, Evening Mail (Jersey), Mining Journal, Le Courrier de la Presse, Local Government Chronicle, Hertfordshire Mercury, West Middlesex Standard, Weekly Free Press and Aberdeen Herald, Reading Mercury, Lymington Chronicle, Eastern Daily Press (Norwich), Surrey Advertiser, Cork Daily Herald, Walton News, Guy's Hospital Gazette, Brighton Examiner, Australian Medical Gazette, Deal, Walmer, and Sandwich Mercury, Newcastle Daily Chronicle, East Essex Advertiser, Eastern Morning News, East Dorset Herald, Grantham Journal, Public Health, Sheffield Daily Telegraph, &c., &c.*

Terms for Position Pages and Serial Insertions on application.

NOTICE.—Advertisers are requested to observe that it is contrary to the Postal Regulations to receive at Post Offices letters addressed to fictitious names or initials only.

An original and novel feature of "THE LANCET General Advertiser" is a special Index to Advertisements on pages 2 and 4, which not only affords a ready means of finding any notice, but is in itself an *additional* advertisement.

Advertisements (to ensure insertion the same week) should be delivered at the Office not later than Wednesday, accompanied by a remittance.

Answers are now received at this Office, by special arrangement, to Advertisements appearing in THE LANCET.

The Manager cannot hold himself responsible for the return of testimonials &c. sent to the Office in reply to advertisements; copies only should be forwarded.

Terms for Serial Insertions may be obtained of the Manager, to whom all letters relating to Advertisements or Subscriptions should be addressed.

THE LANCET can be obtained at all Messrs. W. H. Smith and Son's and other Railway Bookstalls throughout the United Kingdom. Advertisements are also received by them and all other Advertising Agents.

Agent for the Advertisement Department in France—J. ASTIER, 8, Rue Traversière, Asnières, Paris.

A Lecture
ON
ATHEROMA AND SOME OF ITS CONSEQUENCES, WITH THEIR TREATMENT.

Delivered before the Cardiff Medical Society on Feb. 21st, 1895,

By T. LAUDER BRUNTON, M.D., F.R.S.,
PHYSICIAN TO, AND LECTURER ON PHARMACOLOGY AND THERAPEUTICS AT, ST. BARTHOLOMEW'S HOSPITAL.

MR. PRESIDENT AND GENTLEMEN,—When I was asked to address this society I was told that a subject of practical interest would be best appreciated, and I have accordingly chosen one which is not only of interest to us as medical men, but either is now or will be by-and-by of interest to us personally, for if we live long enough few of us are likely to escape atheroma and its consequences. It is a trite proverb that "the strength of a chain is that of its weakest link," and the same idea has been applied to man in the saying that "a man is as old as his vessels." In this phrase we have, in the first place, an acknowledgment that the different parts of a man do not all age at the same rate, but that some grow feeble and old before the rest; and, secondly, that the vessels are especially apt to grow old early, and upon their strength or feebleness the fate of the whole organism hangs. Nor is it only in the relative ageing of the vessels as compared with other tissues that a difference is to be remarked, for it occurs also in different parts of the vascular system. Sometimes it is the aorta which becomes affected, while the smaller arteries remain comparatively free. At other times it is the small arteries which become affected, while the aorta remains healthy. Consequently, the symptoms which result from atheromatous disease of the vascular system may differ much, but there are two great groups which come prominently forward—namely, those in which the symptoms are cardiac and those in which they are cerebral. The cardiac affections are chiefly connected with atheroma of the aorta. The cerebral symptoms, although usually associated with atheroma of the vessels in the brain, may also be due to alterations in the aorta and in the heart itself. The atheromatous process is so common in old age that it is usually regarded as a necessary concomitant of advancing years. It has been compared by Virchow to chronic arthritis of the joints and has been called by him "arteritis deformans," while he calls the joint affection "arthritis deformans." But while a certain amount of atheroma is almost invariably associated with advancing years, the arteries may become atheromatous at an earlier age in consequence of disordered nervous supply or disordered tissue change and elimination. Thus it has been found experimentally by Lewaschew[1] that irritation of nerves leads to changes in the vessels which they supply, the vasa vasorum being at first dilated and afterwards the middle coat becoming displaced by connective tissue, so that the internal coat and adventitia become blended. Clinical observation also shows very strikingly how mental worry affects the vessels and how frequently in elderly people it is followed by vascular changes. Altered nutrition also affects the vessels enormously, and, although atheroma may occur to a very great extent apart from syphilis, yet this disease certainly leads very frequently to endarteritis and vascular degeneration, with weakening of the large vessels or occlusion of the smaller. Endarteritis has also been produced experimentally by lesion of the kidneys, leading to their contraction, and the atheroma which is so frequently found along with contracted kidney may, as I hope to show, be actually dependent to a certain extent on that condition. The process of atheroma is thus described by Ziegler:[2] "The intima is generally the most affected, while the media is often unaltered and the adventitia only slightly infiltrated. In other cases the adventitia may be somewhat thickened and the media atrophied. The change in the intima consists of more or less extensive but generally unilateral thickening. At the points where the altered passes into the unaltered tissue the thickening is made up of fibrous tissue more or less notably infiltrated with leucocytes. The same is true of the innermost layers of the altered intima; but the deeper layers in contact with the elastic bounding membrane consist of pale indistinctly fibrillated tissue, which is devoid of nuclei and almost entirely necrosed; they contain numerous aggregations of granular detritus. The granular masses consist partly of albumin, partly of fat, and older foci of softening nearly always contain tablets of cholesterin. Atheroma thus appears to be essentially a necrosis with granular and fatty disintegration of the thickened intima. The atheromatous ulcer is produced by the advance of the disintegrating process towards the lumen of the vessel and rupture of the innermost layers of the intima. We may conceive how readily such a rupture might occur if we note that on the post-mortem table very slight

FIG. 1.

After Ziegler. Section of an atheromatous cerebral artery. *a*, Intima considerably thickened. *b*, Bounding elastic lamella of intima. *c*, Media. *d*, Adventitia. *e*, Necrosed denucleated tissue with masses of fatty detritus. *f* and *f*, Detritus with cholesterin tablets. *g*, Infiltrated leucocytes in the intima. *h*, Infiltrated leucocytes in the adventitia.

pressure on an atheromatous patch often suffices to break in the surface layer and convert the patch into a cavity." Sometimes the atheromatous patch, either while whole or after undergoing ulceration, may become more or less calcified, and the sharp points of the calcareous plates may not only make their presence evident to the auscultator's ear by giving rise to a sharp whizzing murmur over the aorta, but may lead to the production of fibrinous clots by a process analogous to that of whipping blood after it has been shed. Along with atheroma it may be advisable to take endarteritis obliterans, which is practically atheroma in the smaller vessels, and consists, like it, in a thickening of the internal coat, though possibly with less deposit between the internal and middle coats than what we find in atheroma of the larger arteries. I shall therefore class it along with atheroma and use this term as more convenient when talking both of the affections of the large and of the minute arteries.
